AWS Neuron is the SDK used to run deep learning workloads on AWS Inferentia and AWS Trainium based instances. It supports customers in their end-to-end ML development lifecycle to build new models, train and optimize these models, and then deploy them for production. To learn about the model architectures currently supported on Inf1 and Trn1 instances, please see *Model Architecture Fit Guidelines*. To learn about upcoming capabilities, please view the *Roadmap*.

AWS Neuron includes a deep learning compiler, runtime, and tools that are natively integrated into TensorFlow, PyTorch and Apache MXNet (incubating). The EC2 Trn1 instances are optimized for the highest performance and best price-performance training in AWS. The EC2 Inf1 instances are designed for high-performance deep learning inference applications. With Neuron, customers can quickly start using Inf/Trn instances through services like Amazon Sagemaker, Amazon Elastic Container Service (ECS), Amazon Elastic Kubernetes Service (EKS), AWS Batch, and AWS Parallel Cluster.

Check *Annoucements* and check *Neuron 2.6.0 (12/12/2022)* for latest release.

CHAPTER

TWO

GET STARTED WITH PYTORCH NEURON

This page provide links that will assist you to quickly start with *PyTorch Neuron* for both Inference and Training.

Get Started with Training

Launch Trn1 Instance

- Please follow the instructions at launch an Amazon EC2 Instance to Launch an Trn1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Trn1 instances sizes and pricing see Trn1 web page.
- Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Amazon Linux 2 AMI(HVM) - Kernel 5.10.
- When launching a Trn1, please adjust your primary EBS volume size to a minimum of 512GB.
- After launching the instance, follow the instructions in Connect to your instance to connect to the instance

Important: AutoScalingGroups is currently not supported on Trn1 and will be added soon.

To launch a Trn1 cluster you can use AWS ParallelCluster, please see example.

Note: Neuron Driver installed on Deep Learning AMI (DLAMI) with Conda does not support Trn1.

If you want to use DLAMI with Conda, please make sure to uninstall `aws-neuron-dkms` and install `aws-neuronx-dkms` before using Neuron on DLAMI with Conda.

Install Drivers and Tools

```
# Configure Linux for Neuron repository updates

sudo tee /etc/yum.repos.d/neuron.repo > /dev/null <<EOF
[neuron]
name=Neuron YUM Repository
baseurl=https://yum.repos.neuron.amazonaws.com
enabled=1
metadata_expire=0
EOF
sudo rpm --import https://yum.repos.neuron.amazonaws.com/GPG-PUB-KEY-AMAZON-AWS-NEURON.
→PUB
```

(continues on next page)

(continued from previous page)

```
# Update OS packages
sudo yum update -y

# Install git
sudo yum install git -y

# Install OS headers
sudo yum install kernel-devel-$(uname -r) kernel-headers-$(uname -r) -y

WHAT'S NEW

Table of contents

- *Neuron 2.6.0 (12/12/2022)*
- *Previous Releases*

6.1 Neuron 2.6.0 (12/12/2022)

Table of contents

- *What's New*
- *Neuron Components Release Notes*
  - *Inf1 and Trn1 common packages*
  - *Trn1 only packages*
  - *Inf1 only packages*

6.1.1 What's New

This release introduces the support of PyTorch 1.12 version, and introduces PyTorch Neuron (`torch-neuronx`) profiling through Neuron Plugin for TensorBoard. Pytorch Neuron (`torch-neuronx`) users can now profile their models through the following TensorBoard views:

- Operator Framework View
- Operator HLO View
- Operator Trace View

This release introduces the support of LAMB optimizer for FP32 mode, and adds support for *capturing snapshots* of inputs, outputs and graph HLO for debugging.

In addition, this release introduces the support of new operators and resolves issues that improve stability for Trn1 customers.

For more detailed release notes of the new features and resolved issues, see *Neuron Components Release Notes*.

6.1.2 Neuron Components Release Notes

Inf1 and Trn1 common packages

Component	Instance/s	Package/s	Details
Neuron Runtime	Trn1 , Inf1	• Trn1: `aws-neuronx-runtime-lib` (.deb, .rpm) • Inf1: Runtime is linked into the ML frameworks packages	• *Neuron Runtime Release Notes*
Neuron Runtime Driver	Trn1, Inf1	• `aws-neuronx-dkms` (.deb, .rpm)	• *Neuron Driver Release Notes*
Neuron System Tools	Trn1, Inf1	• `aws-neuronx-tools` (.deb, .rpm)	• *Neuron System Tools*
Containers	Trn1, Inf1	• `aws-neuronx-k8-plugin` (.deb, .rpm) • `aws-neuronx-k8-scheduler` (.deb, .rpm) • `aws-neuronx-oci-hooks` (.deb, .rpm)	• *Neuron K8 Release Notes* • *Neuron Containers Release Notes*
NeuronPerf (Inference only)	Trn1, Inf1	• `neuronperf` (.whl)	• neuronperf_rn

Trn1 only packages

Component	Instance/s	Package/s	Details
PyTorch Neuron	Trn1	• `torch-neuronx` (.whl)	• *PyTorch Neuron (torch-neuronx) release notes* • *PyTorch Neuron (torch-neuronx) - Training Supported Operators*
Neuron Compiler (Trn1 only)	Trn1	• `neuronx-cc` (.whl)	• *Neuron Compiler (neuronx-cc) release notes*
Collective Communication library	Trn1	• `aws-neuronx-collective` (.deb, .rpm)	• *Neuron Collectives Release Notes*

Note: In next releases `aws-neuronx-tools` and `aws-neuronx-runtime-lib` will add support for Inf1.

Inf1 only packages

Component	Instance/s	Package/s	Details
PyTorch Neuron	Inf1	• `torch-neuron` (.whl)	• *PyTorch Neuron (torch-neuron) release notes* • *PyTorch Neuron (torch-neuron) Supported operators*
TensorFlow Neuron	Inf1	• `tensorflow-neuron` (.whl)	• *TensorFlow Neuron (tensorflow-neuron (TF1.x)) Release Notes* • *TensorFlow Neuron (tensorflow-neuron (TF1.x)) Supported operators*
TensorFlow Model Server Neuron	Inf1	• `tensorflow-model-server-neuronx` (.deb, .rpm)	• tensorflow-modelserver-rn
Apache MXNet (Incubating)	Inf1	• `mx_neuron` (.whl)	• *Apache MXNet Neuron (Incubating) Release Notes* • *Neuron Apache MXNet (Incubating) Supported operators*
Neuron Compiler (Inf1 only)	Inf1	• `neuron-cc` (.whl)	• *Neuron Compiler (neuron-cc) for Inf1 Release Notes* • *Neuron Supported operators*

CHAPTER

EIGHT

PYTORCH NEURON

PyTorch Neuron unlocks high-performance and cost-effective deep learning acceleration on AWS Trainium-based and Inferentia-based Amazon EC2 instances.

PyTorch Neuron plugin architecture enables native PyTorch models to be accelerated on Neuron devices, so you can use your existing framework application and get started easily with minimal code changes.

This document is relevant for: `Trn1`

This document is relevant for: `Trn1`

Important: AutoScalingGroups is currently not supported on Trn1 and will be added soon.

To launch a Trn1 cluster you can use AWS ParallelCluster, please see example.

Note: Neuron Driver installed on Deep Learning AMI (DLAMI) with Conda does not support Trn1.

If you want to use DLAMI with Conda, please make sure to uninstall `aws-neuron-dkms` and install `aws-neuronx-dkms` before using Neuron on DLAMI with Conda.

Tutorials (`torch-neuronx`)

This document is relevant for: `Trn1`

8.4 Hugging Face BERT Pretraining Tutorial

This tutorial explains how to run Hugging Face BERT-Large model pretraining on Trainium using PyTorch Neuron.

The Hugging Face BERT pretraining example demonstrates the steps required to perform single-node, multi-accelerator PyTorch model training using the new AWS EC2 Trn1 (Trainium) instances and the AWS Neuron SDK. This tutorial is an adaptation of an existing BERT example with the following important characteristics:

- Framework: PyTorch/XLA
- Model: Hugging Face BertForPreTraining
- Optimizer: AdamW
- Scheduler: Hugging Face's get_linear_schedule_with_warmup
- Allreduce occurs before optimizer step, after gradient accumulations (following DeepSpeed's Smart Gradient Accumulation)

As done in the original BERT paper, BERT pretraining happens in two phases. In the first phase (phase 1) BERT maximum sequence length is fixed at 128 tokens, while in phase 2 it is fixed at 512 tokens.

Neuron provides access to Trainium devices through an extension of PyTorch/XLA - a library that includes the familiar PyTorch interface along with XLA-specific additions. For additional details relating to PyTorch/XLA, please refer to the official PyTorch/XLA documentation.

8.4.1 Phase 1 BERT-Large pretraining

Setting up the training environment on trn1.32xlarge

The BERT training script `dp_bert_large_hf_pretrain_hdf5.py` can run on a Trainium instance (trn1.32xlarge) that contains the appropriate Neuron runtime and Python dependencies.

First, on a trn1.32xlarge instance, follow the installation instructions at:

- *Install PyTorch Neuron on Trn1*

Please set the storage of instance to *512GB* or more if you intent to run multiple experiments and save many checkpoints.

For all the commands below, make sure you are in the virtual environment that you have created above before you run the commands:

```
source ~/aws_neuron_venv_pytorch/bin/activate
```

Next, download the Python-based training script `dp_bert_large_hf_pretrain_hdf5.py` and `requirements.txt` and install the requirements:

```
mkdir -p ~/examples/dp_bert_hf_pretrain
cd ~/examples/dp_bert_hf_pretrain
wget https://raw.githubusercontent.com/aws-neuron/aws-neuron-samples/master/torch-
↪neuronx/training/dp_bert_hf_pretrain/dp_bert_large_hf_pretrain_hdf5.py
wget https://raw.githubusercontent.com/aws-neuron/aws-neuron-samples/master/torch-
↪neuronx/training/dp_bert_hf_pretrain/requirements.txt
```

(continues on next page)

(continued from previous page)

```
python3 -m pip install -r requirements.txt
```

Downloading tokenized and sharded dataset files

To download the tokenized and sharded dataset files needed for this tutorial, please run the following commands:

```
mkdir -p ~/examples_datasets/
pushd ~/examples_datasets/
aws s3 cp s3://neuron-s3/training_datasets/bert_pretrain_wikicorpus_tokenized_hdf5/bert_
↪pretrain_wikicorpus_tokenized_hdf5_seqlen128.tar .  --no-sign-request
tar -xf bert_pretrain_wikicorpus_tokenized_hdf5_seqlen128.tar
rm bert_pretrain_wikicorpus_tokenized_hdf5_seqlen128.tar
aws s3 cp s3://neuron-s3/training_datasets/bert_pretrain_wikicorpus_tokenized_hdf5/bert_
↪pretrain_wikicorpus_tokenized_hdf5_seqlen512.tar .  --no-sign-request
tar -xf bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512.tar
rm bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512.tar
popd
```

`~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen128` will now have the tokenized and sharded dataset files for phase 1 pretraining and `~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512` for phase 2 pretraining.

Number of workers

You will be using torchrun (PyTorch's Elastic Launch) to run some of the commands in this tutorial. When running the training script, you can configure the number of NeuronCores to use for training by using torchrun's `--nproc_per_node` option. In this tutorial, we use 32 NeuronCores on trn1.32xlarge.

Note: Currently Neuron Runtime only support 1 and 2 worker configurations on trn1.2xlarge and 1, 2, 8, and 32-worker configurations on trn1.32xlarge.

BFloat16 and stochastic rounding in phase 1

Phase 1 pretraining performance can be increased by using full BFloat16 casting and stochastic rounding. Full BFloat16 casting and stochastic rounding can be enabled by setting environment variable `XLA_USE_BF16=1` when launching the pretraining job. `XLA_DOWNCAST_BF16=1` can also be used instead of `XLA_USE_BF16=1` to preserve part of the training loop in FP32. Here we use `XLA_DOWNCAST_BF16=1` to ensure smooth loss curve when loss averaging is used. To achieve maximum performance while maintaining loss convergence characteristics, we are using batch size of 16 and gradient accumulation microsteps of 32 to maintain global batch size of 16384 for phase 1. The batch size and gradient accumulation microstep changes can be set by launching the BERT pretraining script `dp_bert_large_hf_pretrain_hdf5.py` with command-line arguments `--batch_size=16 --grad_accum_usteps=32`, as seen in the following steps.

Pre-compilation

PyTorch Neuron evaluates operations lazily during execution of the training loops, which means it builds a symbolic graph in the background and the graph is executed in hardware only when the tensor is printed, transfered to CPU, or `xm.mark_step()` is encountered (`xm.mark_step()` is implicitly called by `pl.MpDeviceLoader/pl.ParallelLoader`). During execution of the training loops, PyTorch Neuron can build multiple graphs depending on the number of conditional paths taken. For BERT-Large pretraining, PyTorch Neuron builds multiple unique graphs that should be compiled before running on the NeuronCores. PyTorch Neuron will compile those graphs only if they are not in the XLA in-memory cache or the persistent cache. To reduce the compilation time of these graphs, you can pre-compile those graphs using the utility `neuron_parallel_compile` (provided by the `libneuronxla` package, a transitive dependency of `torch-neuronx`) as shown:

```
cd ~/examples/dp_bert_hf_pretrain
neuron_parallel_compile XLA_DOWNCAST_BF16=1 torchrun --nproc_per_node=32 \
dp_bert_large_hf_pretrain_hdf5.py \
--steps_this_run 10 \
--batch_size 16 \
--grad_accum_usteps 32 |& tee compile_log.txt
```

This command performs a fast trial run of the training script to build graphs and then do parallel compilations on those graphs using multiple processes of Neuron Compiler before populating the on-disk persistent cache with compiled graphs. This helps make the actual training run faster because the compiled graphs will loaded from the persistent cache. Currently it takes ~13 minutes to compile the BERT-Large model training step using the pre-compilation script (compare to ~40 minute if not using the pre-compilation script). Note that the command above specifies 32 NeuronCores for trn1.32xlarge via –nproc_per_node option.

The pretokenized dataset is expected to be at `~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen128/` by default (see above for downloading instructions) and can be changed via the `--data_dir` option.

Note: The trial run during pre-compilation currently outputs invalid loss numbers. Please disregard them.

Note: The command after `neuron_parallel_compile` should match the actual run command, except for the option `--steps_this_run` which shortens the trial run just enough to allow the tool to build all the graphs needed for the actual run.

If you interrupt the run and restart the execution without changing model configurations or training hyperparameters, the new run will detect the cached graphs in the persistent cache (on-disk) and reload the compiled graphs for execution, avoiding any recompilation time.

Changes made to the BERT model configuration (layers, hidden size, attention heads in the get_model function), batch size (using `--batch_size` option), optimizer or number of workers may trigger graph recompilation. It is best to rerun the pre-compilation step above if these changes are made.

You can adjust the following hyperparameters without changing the model and causing recompilation:

- Number of global steps to run (`--steps_this_run` option)
- Learning rate (`--lr` option)
- Gradient accumulation steps > 1 (`--grad_accum_usteps` option). If 1 then there's no gradient accumulation and the graphs change causing recompilation.

Initiating a Training Job

After running the pre-compilation step, continue with the actual phase 1 pretraining by running the following set of commands to launch 32 data parallel distributed training workers on trn1.32xlarge:

```
cd ~/examples/dp_bert_hf_pretrain
XLA_DOWNCAST_BF16=1 torchrun --nproc_per_node=32 \
dp_bert_large_hf_pretrain_hdf5.py \
--batch_size 16 \
--grad_accum_usteps 32 |& tee run_pretrain_log.txt
```

As the training script launches, you will initially see several console messages indicating that the Neuron Runtime is initializing:

```
Using Neuron Runtime
Using Neuron Runtime
Using Neuron Runtime
Using Neuron Runtime
Using Neuron Runtime
...
```

A few moments later, you will see the Training Configuration and Model Configuration in the output:

```
--------TRAINING CONFIG----------
Namespace(batch_size=16, data_dir='~/examples_datasets/
bert_pretrain_wikicorpus_tokenized_hdf5_seqlen128/', debug=False,
enable_pt_autocast=False, grad_accum_usteps=32, local_rank=0, lr=0.0004,
max_pred_len=20, max_steps=28125, metrics_file='/tmp/test_dict.json',
minimal_ckpt=False, num_ckpts_to_keep=1, output_dir='./output',
phase1_end_step=28125, phase2=False, resume_ckpt=False, resume_step=-1,
seed=12349, seq_len=128, shards_per_ckpt=1, steps_this_run=28125, warmup_steps=2000)
```

```
--------MODEL CONFIG----------
BertConfig {
"_name_or_path": "bert-large-uncased",

↪throughput : 2875.31
LOG Thu Sep 29 22:30:27 2022 - (0, 81) step_loss : 9.0000  learning_rate : 1.62e-05 ␣
↪throughput : 2877.35
LOG Thu Sep 29 22:30:33 2022 - (0, 82) step_loss : 8.8750  learning_rate : 1.64e-05 ␣
↪throughput : 2872.55
LOG Thu Sep 29 22:30:39 2022 - (0, 83) step_loss : 9.0000  learning_rate : 1.66e-05 ␣
↪throughput : 2876.17
LOG Thu Sep 29 22:30:44 2022 - (0, 84) step_loss : 9.1250  learning_rate : 1.68e-05 ␣
↪throughput : 2872.48
LOG Thu Sep 29 22:30:50 2022 - (0, 85) step_loss : 9.0000  learning_rate : 1.70e-05 ␣
↪throughput : 2873.39
```

By default, the training script will store all output files under `~/examples/dp_bert_hf_pretrain/output`. The output files consist of the following:

- PyTorch model checkpoint files, with names containing the global step of the checkpoint (ckpt_2000.pt, ckpt_4000.pt, etc.). Currently, the training script saves a checkpoint after every dataset shard. The frequency of saving checkpoint can be reduced by increasing the number of dataset shards per checkpoint, using option `--shards_per_ckpt`. Furthermore, the number of checkpoints kept at a given time is limited by `--num_ckpts_to_keep` option (currently default to 1).
- TensorBoard log files (each training run will store its logs in a subdirectory with prefix `neuron_tblogs_`).

Monitoring Progress of the Training Job

Using a single Trn1 instance with 32 NeuronCores, the current BERT phase 1 pretraining will finish in about 45 hours. During this time, you will see the average loss metric begin at about 11.2 and ultimately converge to about 1.4.

Monitoring Training Job Progress using neuron-top

With the training job still running, launch a second SSH connection into the trn1 instance, and use the `neuron-top` command to examine the aggregate NeuronCore utilization. If you have not modified the `--nproc_per_node` option in the run command, you should observe that all 32 NeuronCores are participating in the training job, with utilization fluctuating around 80%.

Monitoring Training Job Progress using TensorBoard

The demo includes TensorBoard-compatible logging, which allows the learning rate and training metrics to be monitored in real-time. By default, the training script logs metrics to the following TensorBoard log directory `~/examples/dp_bert_hf_pretrain/output/neuron_tblogs_<date/time>_<training configs>`.

In order to view your training metrics in TensorBoard, first run the following commands in your SSH session:

```
cd ~/examples/dp_bert_hf_pretrain
tensorboard --logdir ./output
```

Once running, open a new SSH connection to the instance and port-forward TCP port 6006 (ex: `-L 6006:127.0.0.1:6006`). Once the tunnel is established, TensorBoard can then be accessed via web browser at the following URL: http://localhost:6006. Please note that you will not be able to access TensorBoard if you disconnect your port-forwarding SSH session to the Trainium instance.

Finishing the tutorial

Once you are ready, there are a couple of options for finishing the BERT pretraining demo:

1. **Allow the training script to run to completion**. If you would like to observe the training script run to completion, it is recommended to launch the training script from a terminal multiplexer such as `tmux` or `screen`, and then detach the session so that the training script can run in the background. With this approach, you can safely let the training script run unattended, without risk of an SSH disconnection causing the training job to stop running.
2. **Stop the training job early**. To stop the training job early, press CTRL-C in the terminal window in which you launched the training script. In some cases, if you manually cancel a job using CTRL-C and then later want to run the job again, you might first need to execute `sudo rmmod neuron; sudo modprobe neuron` in order to reload/reset the Neuron driver.

8.4.2 Phase 1 BERT-Large pretraining on two instances

If you have two trn1.32xlarge instances with EFA-enabled interfaces, using EFA-enabled security group, and setup using *Install PyTorch Neuron on Trn1*, you can run multi-instance BERT-Large pretraining. The following example demonstrate running BERT phase 1 pretraining on two instances. To ensure that the global batch size remains at 16384 for phase 1, the gradient accumulation microstep count is reduced by half when the number of instances is 2. NOTE: To run on multiple instances, you will need to use trn1.32xlarge instances and using all 32 NeuronCores on each instance.

On the rank-0 Trn1 host (root), run with `--node_rank=0` using torchrun utility, and `--master_addr` set to rank-0 host's IP address:

```
cd ~/examples/dp_bert_hf_pretrain
export FI_EFA_USE_DEVICE_RDMA=1
export FI_PROVIDER=efa
export BUCKET_CAP_MB=512
export XLA_TRANSFER_SEED_ASYNC=1
XLA_DOWNCAST_BF16=1 torchrun --nproc_per_node=32 --nnodes=2 --node_rank=0 --master_addr=
↪<root IP> --master_port=2020 \
dp_bert_large_hf_pretrain_hdf5.py \
--batch_size 16 \
--grad_accum_usteps 16 |& tee run_pretrain_log.txt
```

On another Trn1 host, run with `--node_rank=1`, and `--master_addr` also set to rank-0 host's IP address:

```
cd ~/examples/dp_bert_hf_pretrain
export FI_EFA_USE_DEVICE_RDMA=1
export FI_PROVIDER=efa
export BUCKET_CAP_MB=512
export XLA_TRANSFER_SEED_ASYNC=1
XLA_DOWNCAST_BF16=1 torchrun --nproc_per_node=32 --nnodes=2 --node_rank=1 --master_addr=
↪<root IP> --master_port=2020 \
dp_bert_large_hf_pretrain_hdf5.py \
--batch_size 16 \
--grad_accum_usteps 16 |& tee run_pretrain_log.txt
```

It is important to launch rank-0 worker with `--node_rank=0` to avoid hang.

To train on multiple instances, it is recommended to use a ParallelCluster. For a ParallelCluster example, please see Train a model on AWS Trn1 ParallelCluster.

8.4.3 Phase 2 BERT-Large pretraining

As mentioned above, BERT pretraining happens in two phases. In phase 1, the sequence length is 128. In phase 2, the sequence length increases to 512. This additional training phase will further reduce the pretraining loss and improve the metrics for the fine-tune tasks that usually follow. The setup is very similar to the phase 1, with some differences in training environment and command line arguments highlighted below.

Training Environment

The following dataset and checkpoint are required:

- `~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512` is WikiCorpus training dataset that is preprocessed (tokenized and pre-masked) for phase 2.
- `~/examples/dp_bert_hf_pretrain/output/ckpt_<phase1_end_step>.pt` is the final checkpoint from phase 1. It's generated automatically at the end of phase 1 pretraining. For convenience, one can also download the example available at `s3://neuron-s3/training_checkpoints/pytorch/dp_bert_large_hf_pretrain/ckpt_28125.pt`, which is collected after 28125 training steps in phase 1. Phase 2 will continue training by loading this checkpoint. During its progression, phase 2 continues to generate its own checkpoints in output directory, following the naming convention `ckpt_<global_steps>.pt`

Initiating a Training Job

To launch the phase 2 pretraining job, run the same python script `dp_bert_large_hf_pretrain_hdf5.py` as before except with different options for phase 2. Again, we are using BFloat16 casting and stochastic rounding by setting environment variable `XLA_DOWNCAST_BF16=1`. For phase 2, we are using global batch size of 32768, with worker device batch size of 2 and gradient accumulation microsteps of 512. The pretokenized dataset is expected to be at `~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512/` following the setup steps above and is set via `--data_dir` option.

```
cd ~/examples/dp_bert_hf_pretrain
XLA_DOWNCAST_BF16=1 torchrun --nproc_per_node=32 dp_bert_large_hf_pretrain_hdf5.py \
    --data_dir ~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512/ \
    --lr 2.8e-4 \
    --phase2 \
    --resume_ckpt \
    --phase1_end_step 28125 \
    --batch_size 2 \
    --grad_accum_usteps 512 \
    --seq_len 512 \
    --max_pred_len 80 \
    --warmup_steps 781 \
    --max_steps 1563 \
    |& tee run_pretrain_log_phase2.txt
```

The output below is expected as the job is initiated. Step 28125 is the phase1_end_step in this run, which could be different if phase1 training stops at a different global step.

```
Worker 21 resuming from checkpoint ./output/ckpt_28125.pt at step 28125
Worker 23 resuming from checkpoint ./output/ckpt_28125.pt at step 28125
Worker 27 resuming from checkpoint ./output/ckpt_28125.pt at step 28125
Worker 26 resuming from checkpoint ./output/ckpt_28125.pt at step 28125
Worker 20 resuming from checkpoint ./output/ckpt_28125.pt at step 28125
```

(continues on next page)

(continued from previous page)

```
Worker 22 resuming from checkpoint ./output/ckpt_28125.pt at step 28125

--------TRAINING CONFIG----------
Namespace(batch_size=2, data_dir='/home/ec2-user/examples_datasets/

8.4.4 Tools

While running the tutorial, try experimenting with the following Neuron tools, which help monitor and evaluate compute utilization in real-time:

neuron-ls

The `neuron-ls` command describes the number of Neuron devices present in the system, along with the associated NeuronCore count, memory, and PCI device information:

```
[ec2-user@ip-10-0-1-68 ~]$ neuron-ls
Neuron Tools have changed with Neuron v1.16.0. Go here to learn more:
https://awsdocs-neuron.readthedocs-hosted.com/en/latest/neuron-guide/neuron-tools/

If you're still running Neuron Runtime 1.0, run this program as sudo to display neuron-rtd
runtime information

[ec2-user@ip-10-0-1-68 ~]$
```

You will find that the Trn1 instance has 16 Neuron devices, each with 2 NeuronCores. This configuration allows you to train the model using a total of 32 workers, one per NeuronCore, within a single instance.

Additional information regarding neuron-ls can be found in the neuron-ls user guide.

neuron-top

The `neuron-top` command presents a high-level view of the Neuron environment, including the utilization of each of the NeuronCores, any models that are currently loaded onto one or more NeuronCores, process IDs for any processes that are leveraging the Neuron runtime, and basic system statistics relating to vCPU and memory usage.

Please note that `neuron-top` can either display aggregate NeuronCore utilization for 'all' processes (the default), or alternatively display the NeuronCore utilization for a particular process. You can toggle through the aggregate and per-process views using the `a` and `d` keys. The screenshot below illustrates the default aggregate view:

Please refer to the neuron-top user guide for additional details.

Generating tokenized and sharded dataset files

This section is for generating tokenized and sharded dataset files from WikiCorpus dataset. If you just want the pre-genenerated dataset files, please see `Downloading tokenized and sharded dataset files` section above.

On a c5n.18xlarge instance launched with Deep Learning Conda AMI and 512GB disk space, you can generate the preprocessed datasets from WikiCorpus dataset using NVidia's DeepLearningExamples for BERT pretraining. The preprocessing converts the WikiCorpus dataset to tokenized data and shard the data into multiple shards for parallel loading. The full flow takes about 8.7 hours:

```
source activate pytorch_latest_p37
cd ~/
git clone https://github.com/NVIDIA/DeepLearningExamples.git
cd DeepLearningExamples
git checkout 81b9010096b6f9812e3977b607669f6ec8b16561
sudo mkdir -m a=rwx /workspace
cp -rf PyTorch/LanguageModeling/BERT /workspace/bert
cd /workspace
git clone https://github.com/attardi/wikiextractor.git
cd wikiextractor
git checkout 6408a430fc504a38b04d37ce5e7fc740191dee16
cd /workspace/bert
# increase num processes and shards
ex -s "+%s/\(bertPrep\.py\)\( --action create_hdf5_files\)/\1 --n_processes 32 --n_test_
↪shards 1024 --n_training_shards 1024\2" "+wq" data/create_datasets_from_start.sh
export BERT_PREP_WORKING_DIR=/workspace/data/
time ./data/create_datasets_from_start.sh wiki_only |& tee log
```

After execution is finished, phase 1 pre-tokenized and sharded dataset is located at:

`/workspace/data/hdf5_lower_case_1_seq_len_128_max_pred_20_masked_lm_prob_0.15_random_seed_12345_dupe_factor_5/wikicorpus_en/`

Copy this entire directory to `~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen128` of the trn1.32xlarge machine.

Phase 2 pre-tokenized dataset is located at:

`/workspace/data/hdf5_lower_case_1_seq_len_512_max_pred_80_masked_lm_prob_0.15_random_seed_12345_dupe_factor_5/wikicorpus_en/`

Copy this entire directory to `~/examples_datasets/bert_pretrain_wikicorpus_tokenized_hdf5_seqlen512` of the trn1.32xlarge machine.

8.4.5 Known issues and limitations

NaNs seen with transformers version >= 4.21.0 when running HF BERT fine-tuning or pretraining with XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1

When running HuggingFace BERT (any size) fine-tuning tutorial or pretraining tutorial with transformers version >= 4.21.0 and using XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1, you will see NaNs in the loss immediately at the first step. More details on the issue can be found at pytorch/xla#4152. The workaround is to use 4.20.0 or earlier (the tutorials currently recommend version 4.15.0) or add `transformers.modeling_utils.get_parameter_dtype = lambda x: torch.bfloat16` to the Python script.

BERT-large compilation limitations

Optimal BERT-large phase 1 (sequence length 128) batch size is currently 8 for FP32 and 16 for full BF16 with stochastic rounding. Optimal BERT-large phase 2 (sequence length 512) batch size is currently 1 for FP32 and 2 for full BF16 with stochastic rounding.

BERT-large pretraining with pretokenized dataset hangs when using xm.save

Currently, BERT-large pretraining with pretokenized dataset hangs when `xm.save` is used outside of the main training loop.

```
Loop through HDF5 sharded dataset files:
    Train on one HDF5 sharded dataset file
        Loop through batched samples:
            Training iteration
    Save checkpoint using xm.save
```

The reason is that xm.save has a synchronization point. However, the HDF5 shared data files do not have the same number of training samples so the workers cannot all reach xm.save in the same iteration.

The workaround is to use `xm._maybe_convert_to_cpu` to ensure tensors are moved to CPU followed by `torch.save` as done in the BERT-large pretraining tutorial:

```
cpu_data = xm._maybe_convert_to_cpu(data)
```

BERT-large two worker pretraining hangs or run out of host memory during checkpointing on trn1.2xlarge

On trn1.2xlarge, where there's limited host memory and CPU resources, the BERT-large two worker pretraining may hang or run out of host memory during checkpointing. This problem can be worked around by not saving optimizer and LR scheduler states in the checkpoint. This is enabled by `--minimal_ckpt` option of the pretraining script.

BERT precompilation using neuron_parallel_compile hangs when using torchrun

We use neuron_parallel_compile in front of the short run command to do precompilation. However, the following command hangs when running BERT parallel compilation with torchrun:

```
neuron_parallel_compile XLA_USE_BF16=1 torchrun --nproc_per_node=32 --nnodes=1 dp_bert_
↪large_hf_pretrain_hdf5.py --steps_this_run 5

...
Updating train metrics in provide results.json file
Current data: {'num_workers': 32, 'epoch': 0, 'steps': 5, 'microsteps': 320, 'loss': -
↪22172234.0, 'train_time_minutes': 0.7424166639645894, 'throughput_average': 1839.
↪0391805624324, 'throughput_peak': 1840.0107059878164, 'batch_size': 8, 'max_length':␣
↪128}
Updating with data: {'num_workers': 32, 'epoch': 0, 'steps': 5, 'microsteps': 320, 'loss
↪': -22172234.0, 'train_time_minutes': 0.7826640844345093, 'throughput_average': 1744.
↪4691285659471, 'throughput_peak': 1745.4964663587539, 'batch_size': 8, 'max_length':␣
↪128}
Checkpointing...
Checkpointing done...
(hangs)
```

The fix is to add xm.rendezvous at the end of training to ensure all workers sync up before exiting the script dp_bert_large_pretrain_hdf5.py.

```
def _mp_fn(index, flags):
    torch.set_default_tensor_type('torch.FloatTensor')
    train_bert_hdf5(flags)
    xm.rendezvous("_mp_fn finished")
```

Reduced multi-node performance with Neuron PyTorch 1.12 (release 2.6)

Default BERT performance on multiple instances is reduced with Neuron PyTorch 1.12 (release 2.6). The workaround is to set the XLA flag XLA_TRANSFER_SEED_ASYNC=1.

8.4.6 Troubleshooting

The following are troubleshooting tips related to this tutorial. See *PyTorch Neuron on Trainium Troubleshooting Guide* for additional troubleshooting tips.

ModuleNotFoundError: No module named 'torch' , 'torch_xla', 'transformers', etc

If you encounter 'ModuleNotFoundError' messages while attempting to run the demo scripts, please ensure that you have activated the appropriate Python *virtualenv* which contains all of the demo dependencies:

```
cd ~
source <python virtual environment path>/bin/activate
```

This document is relevant for: `Trn1`

8.5 Multi-Layer Perceptron Training Tutorial

MNIST is a standard dataset for handwritten digit recognition. A multi-layer perceptron (MLP) model can be trained with MNIST dataset to recognize hand-written digits. This tutorial starts with a 3-layer MLP training example in PyTorch on CPU, then show how to modify it to run on Trainium using PyTorch Neuron. It also shows how to do multiple worker data parallel MLP training.

Table of Contents

- *Setup environment and download examples*
- *Multi-layer perceptron MNIST model*
- *Single-worker MLP training script in PyTorch on CPU*
- *Single-worker MLP training on Trainium*
- *Multi-worker data-parallel MLP training using torchrun*
- *Known issues and limitations*

Note: Logs used in tutorials do not present latest performance numbers

For latest performance numbers visit *Neuron Performance*

8.5.1 Setup environment and download examples

Before running the tutorial please follow the installation instructions at:

- *Install PyTorch Neuron on Trn1*

Please set the storage of instance to *512GB* or more if you also want to run through the BERT pretraining and GPT pretraining tutorials.

For all the commands below, make sure you are in the virtual environment that you have created above before you run the commands:

```
source ~/aws_neuron_venv_pytorch/bin/activate
```

Install needed dependencies in your environment by running:

```
pip install pillow
```

Torchvision package is needed for MNIST dataset and has already been installed as part of *Install PyTorch Neuron on Trn1*. Installing Torchvision together with torch-neuronx ensures that the compatible version of Torchvision is selected. For example, torchvision==0.12 is compatible with torch==1.11 and torchvision==0.13 is compatible with torch==1.12.

To download the MNIST MLP examples, do:

```
git clone https://github.com/aws-neuron/aws-neuron-samples.git
cd aws-neuron-samples/torch-neuronx/training/mnist_mlp
```

8.5.2 Multi-layer perceptron MNIST model

In `model.py`, we define the multi-layer perceptron (MLP) MNIST model with 3 linear layers and ReLU activations, followed by a log-softmax layer. This model will be used in multiple example scripts.

8.5.3 Single-worker MLP training script in PyTorch on CPU

We will show how to modify a training script that runs on other platform to run on Trainium.

We begin with a single-worker MLP training script for running on the host CPUs of the Trainium instance. The training script imports the MLP model from `model.py`.

In this training script, we load the MNIST train dataset and, within the `main()` method, set the data loader to read batches of 32 training examples and corresponding labels.

Next we instantiate the MLP model and move it to the device. We use `device = 'cpu'` to illustrate the use of device in PyTorch. On GPU you would use `device = 'cuda'` instead.

We also instantiate the other two components of a neural network trainer: stochastic-gradient-descent (SGD) optimizer and negative-log-likelihood (NLL) loss function (also known as cross-entropy loss).

After the optimizer and loss function, we create a training loop to iterate over the training samples and labels, performing the following steps for each batch in each iteration:

- Zero gradients using:

```
optimizer.zero_grad()
```

- Move training samples and labels to device using the 'tensor.to' method.

- Perform forward/prediction pass using

```
output = model(train_x)
```

- The prediction results are compared against the corresponding labels using the loss function to compute the loss

```
loss_fn(output, train_label)
```

- The loss is propagated back through the model using chain-rule to compute the weight gradients

```
loss.backward()
```

- The weights are updated with a change that is proportional to the computed weights gradients

```
optimizer.step()
```

At the end of training we compute the throughput, display the final loss and save the checkpoint.

Expected CPU output:

```
----------Training ---------------
Train throughput (iter/sec): 286.96994718801335
Final loss is 0.1040
----------End Training ---------------
```

For a full tutorial on training in PyTorch, please see https://pytorch.org/tutorials/beginner/introyt/trainingyt.html.

Thus far we have used PyTorch without Trainium. Next, we will show how to change this script to run on Trainium.

8.5.4 Single-worker MLP training on Trainium

To run on Trainium, first we modify the CPU training script train_cpu.py to run with PyTorch Neuron torch_xla as described in *PyTorch Neuron for Trainium Getting Started Guide* by changing the device:

```
import torch_xla.core.xla_model as xm
device = xm.xla_device()
# or
device = 'xla'
```

When the model is moved to the XLA device using `model.to(device)` method, subsequent operations on the model are recorded for later execution. This is XLA's lazy execution which is different from PyTorch's eager execution. Within the training loop, we must mark the graph to be optimized and run on XLA device (NeuronCore) using xm.mark_step() (unless MpDeviceLoader is used as you will see in the next section). Without this mark, XLA cannot determine where the graph ends. The collected computational graph also gets compiled and executed when you request the value of a tensor such as by calling `loss.item()` or `print(loss)`.

To save a checkpoint, it is recommended to use the `xm.save()` function instead of `torch.save()` to ensure states are moved to CPU. `xm.save()` also prevents the "XRT memory handle not found" warning at the end of evaluation script (if the checkpoint saved using torch.save() is used for evaluation).

The resulting script `train.py` can be executed as `python3 train.py`. Again, note that we import the MLP model from `model.py`. When you examine the script, the comments that begin with 'XLA' indicate the changes required to make the script compatible with torch_xla.

Expected output on trn1.32xlarge (start from a fresh compilation cache, located at /var/tmp/neuron-compile-cache by default):

```

----------End Training ---------------
```

Multiple graphs can be created during execution since there are differences between some iterations (first, steady state, last). After the first iteration, the graph for each iteration should remain the same from iteration to iteration. This allows XLA runtime to execute a previous compiled graph that has been cached in XLA runtime cache.

If the inner training loop has some control-flows, for example for gradient accumulation, the number of compiled graphs may increase due to the generation and consumption of intermediates as well as additional operations when the conditional path is taken.

8.5.5 Multi-worker data-parallel MLP training using torchrun

Data parallel training allows you to replicate your script across multiple workers, each worker processing a proportional portion of the dataset, in order to train faster.

The PyTorch distributed utility torchrun can be used to launch multiple processes in a server node for multi-worker data parallel training.

To run multiple workers in data parallel configuration using torchrun, modify the single-worker training script train.py as follows (below we use `xm` as alias for `torch_xla.core.xla_model` and `xmp` as alias for `torch_xla.distributed.xla_multiprocessing`):

1. Import XLA backend for torch.distributed using `import torch_xla.distributed.xla_backend`.
2. Use `torch.distributed.init_process_group('xla')` to initialize PyTorch XLA runtime and Neuron runtime.
3. Use XLA multiprocessing device loader (`MpDeviceLoader`) from `torch_xla.distributed` to wrap PyTorch data loader.
4. Use `xm.optimizer_step(optimizer)` to perform allreduce and take optimizer step.

XLA MpDeviceLoader is optimized for XLA and is recommended for best performance. It also takes care of marking the step for execution (compile and execute the lazily collected operations for an iteration) so no separate `xm.mark_step()` is needed.

The following are general best-practice changes needed to scale up the training:

1. Set the random seed to be the same across workers.
2. Scale up the learning rate by the number of workers. Use `xm.xrt_world_size()` to get the global number of workers.
3. Add distributed sampler to allow different worker to sample different portions of dataset.

Also, the `xm.save()` function used to save checkpoint automatically saves only for the rank-0 worker's parameters.

The resulting script is `train_torchrun.py` (note again that we import the MLP model from `model.py`):

Next we use the `torchrun` utility that is included with torch installation to run multiple processes, each using one NeuronCore. Use the option `nproc_per_node` to indicate the number of processes to launch. For example, to run on two NeuronCores on one Trn1 instance only, do:

```
torchrun --nproc_per_node=2 train_torchrun.py
```

NOTE: Currently we only support 1 and 2 worker configurations on trn1.2xlarge and 1, 2, 8, and 32-worker configurations on trn1.32xlarge.

Expected output on trn1.32xlarge (second run to avoid compilations):

```
----------Training ---------------
----------Training ---------------
... (Info messages truncated)
Train throughput (iter/sec): 163.25353269069706
Train throughput (iter/sec): 163.23261047441036
Final loss is 0.3469
Final loss is 0.1129
----------End Training ---------------
----------End Training ---------------
```

In another example, we run on two trn1.32xlarge instances launched with EFA-enabled interfaces, using EFA-enabled security group, and setup using *Install PyTorch Neuron on Trn1*. NOTE: To run on multiple instances, you will need to use trn1.32xlarge instances and using all 32 NeuronCores on each instance.

On the rank-0 Trn1 host (root), run with `--node_rank=0` using torchrun utility, and `--master_addr` set to rank-0 host's IP address:

```
export FI_EFA_USE_DEVICE_RDMA=1
export FI_PROVIDER=efa
torchrun --nproc_per_node=32 --nnodes=2 --node_rank=0 --master_addr=<root IP> --master_
↪port=2020 train_torchrun.py
```

On another Trn1 host, run with `--node_rank=1`, and `--master_addr` also set to rank-0 host's IP address:

```
export FI_EFA_USE_DEVICE_RDMA=1
export FI_PROVIDER=efa
torchrun --nproc_per_node=32 --nnodes=2 --node_rank=1 --master_addr=<root IP> --master_
↪port=2020 train_torchrun.py
```

It is important to launch rank-0 worker with `--node_rank=0` to avoid hang.

To train on multiple instances, it is recommended to use a ParallelCluster. For a ParallelCluster example, please see Train a model on AWS Trn1 ParallelCluster.

8.5.6 Known issues and limitations

MLP model is not optimized for performance. For the single-worker training, the performance can be improved by using MpDeviceLoader which exists in the multiprocessing example. For example, by setting `--nproc_per_node=1` in the torchrun example, you will see higher MLP performance.

```
(aws_neuron_venv_pytorch_p36) [ec2-user@ip-172-31-69-14 mnist_mlp]$ torchrun --nproc_per_
↪node=1 train_torchrun.py

----------Training ---------------
... (Info messages truncated)
Train throughput (iter/sec): 192.43508922834008
Final loss is 0.2720
----------End Training ---------------
```

This document is relevant for: `Trn1`

This document is relevant for: `Trn1`

8.6 PyTorch Neuron for Trainium Hugging Face BERT MRPC task fine-tuning using Hugging Face Trainer API

In this tutorial, we show how to run a Hugging Face script that uses Hugging Face Trainer API to do fine-tuning on Trainium. The example follows the text-classification example which fine-tunes BERT-base model for sequence classification on the GLUE benchmark.

Table of Contents

- *Setup and compilation*
- *Single-worker training*
- *Multi-worker training*
- *Converting BERT pretrained checkpoint to Hugging Face pretrained model format*
- *Known issues and limitations*

Note: Logs used in tutorials do not present latest performance numbers

For latest performance numbers visit *Neuron Performance*

8.6.1 Setup and compilation

Before running the tutorial please follow the installation instructions at:

- *Install PyTorch Neuron on Trn1*

Please set the storage of instance to *512GB* or more if you also want to run through the BERT pretraining and GPT pretraining tutorials.

For all the commands below, make sure you are in the virtual environment that you have created above before you run the commands:

```
source ~/aws_neuron_venv_pytorch/bin/activate
```

First we install recent version of HF transformers, scikit-learn and evaluate packages in our environment. In this example, we chose version 4.15.0:

```
pip install -U transformers==4.15.0 datasets evaluate scikit-learn
```

Next we download the transformers source, checking out the tag that matches the installed version:

```
cd ~/
git clone https://github.com/huggingface/transformers --branch v4.15.0
```

Go into the examples BERT training directory:

```
cd ~/transformers/examples/pytorch/text-classification
```

Edit the python script run_glue.py and add the following lines after the Python imports. They set the compiler flag for transformer model type and enable data parallel training using torchrun:

```
# Set compiler flag to compile for transformer model type
os.environ["NEURON_CC_FLAGS"] = os.environ.get('NEURON_CC_FLAGS', '') + " --model-
↪type=transformer"

# Enable torchrun
import torch
import torch_xla.distributed.xla_backend
if os.environ.get("WORLD_SIZE"):
    torch.distributed.init_process_group('xla')
```

(continues on next page)

(continued from previous page)

```
# Fixup to enable distributed training with XLA
from packaging import version
from transformers import __version__
if version.parse(__version__) < version.parse("4.20.0"):
    Trainer._wrap_model = lambda self, model, training=True: model
else:
    Trainer._wrap_model = lambda self, model, training=True, dataloader=None: model

# Workaround for NaNs seen with transformers version >= 4.21.0
# https://github.com/aws-neuron/aws-neuron-sdk/issues/593
if os.environ.get("XLA_USE_BF16") or os.environ.get("XLA_DOWNCAST_BF16"):
    transformers.modeling_utils.get_parameter_dtype = lambda x: torch.bfloat16
```

We will run MRPC task fine-tuning following the example in README.md. In this part of the tutorial we will use the Hugging Face model hub's pretrained `bert-large-uncased` model.

We precompile the model and training script to warm up the persistent graph cache (Neuron Cache) such that the actual run has fewer compilations (faster run time). We use full BF16 casting using XLA_USE_BF16=1 to enable best performance. Create a "compile" file with the following content, change it to executable, and run it:

```
export TASK_NAME=mrpc
neuron_parallel_compile XLA_USE_BF16=1 python3 ./run_glue.py \
--model_name_or_path bert-large-uncased \
--task_name $TASK_NAME \
--do_train \
--max_seq_length 128 \
--per_device_train_batch_size 8 \
--learning_rate 2e-5 \
--num_train_epochs 2 \
--overwrite_output_dir \
--output_dir /tmp/$TASK_NAME/ |& tee log_compile_train
```

Note that we separating out the train/eval steps during compilation. Also, we reduce batch size to 8 which is currently optimal for Trainium. Also, to reduce time to extract graph, we limit the trial run to 2 epochs. Please ignore the results from this trial run as it is only for extracting and compiling the XLA graphs.

8.6.2 Single-worker training

After precompilation, the actual run will be faster with minimal additional compilations. NOTE: currently the evaluation step would incur full compilation (see Known Issues below).

To run the actual training, create a "run" file with the following content and run it, again using full BF16 casting (XLA_USE_BF16=1) to enable best performance.:

```
export TASK_NAME=mrpc
XLA_USE_BF16=1 python3 ./run_glue.py \
--model_name_or_path bert-large-uncased \
--task_name $TASK_NAME \
--do_train \
--do_eval \
--max_seq_length 128 \
--per_device_train_batch_size 8 \
```

(continues on next page)

(continued from previous page)

```
--learning_rate 2e-5 \
--num_train_epochs 5 \
--overwrite_output_dir \
--output_dir /tmp/$TASK_NAME/ |& tee log_run
```

Rerunning the same script a second time would show quicker execution as the compiled graphs are already cached in persistent cache.

8.6.3 Multi-worker training

The above script would run one worker on one NeuronCore. To run on multiple cores, run the run_glue.py script with torchrun using `--nproc_per_node=N` option to specify the number of workers (N=2 for trn1.2xlarge, and N=2, 8, or 32 for trn1.32xlarge). The following example runs 2 workers:

```
export TASK_NAME=mrpc
XLA_USE_BF16=1 torchrun --nproc_per_node=2 ./run_glue.py \
--model_name_or_path bert-large-uncased \
--task_name $TASK_NAME \
--do_train \
--do_eval \
--max_seq_length 128 \
--per_device_train_batch_size 8 \
--learning_rate 2e-5 \
--num_train_epochs 5 \
--overwrite_output_dir \
--output_dir /tmp/$TASK_NAME/ |& tee log_run_2w
```

During run, you will notice that the "Total train batch size" is now 16 and the "Total optimization steps" is now half the number for one worker training.

8.6.4 Converting BERT pretrained checkpoint to Hugging Face pretrained model format

If you have a pretrained checkpoint (i.e., from the BERT phase 2 pretraining tutorial), you can run the script below (saved as "convert.py") to convert BERT pretrained saved checkpoint to Hugging Face pretrained model format. An example phase 2 pretrained checkpoint can be downloaded from `s3://neuron-s3/training_checkpoints/pytorch/dp_bert_large_hf_pretrain/ckpt_29688.pt`. Note that here we also use the `bert-large-uncased` model configuration to match the BERT-Large model trained following BERT phase 2 pretraining tutorial.

```
import os
import sys
import argparse
import torch
import transformers
from transformers import (
    BertForPreTraining,
)
import torch_xla.core.xla_model as xm
from transformers.utils import check_min_version
from transformers.utils.versions import require_version
```

(continues on next page)

(continued from previous page)

```
if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('--model_name', type=str, default='bert-large-uncased',  help=
↪"Path to model identifier from huggingface.co/models")
    parser.add_argument('--output_saved_model_path', type=str, default='./hf_saved_model
↪', help="Directory to save the HF pretrained model format.")
    parser.add_argument('--checkpoint_path', type=str, required=True, help="Path to␣
↪pretrained checkpoint which needs to be converted to a HF pretrained model format")
    args = parser.parse_args(sys.argv[1:])

    model = BertForPreTraining.from_pretrained(args.model_name)
    check_point = torch.load(args.checkpoint_path, map_location='cpu')
    model.load_state_dict(check_point['model'], strict=False)
    model.save_pretrained(args.output_saved_model_path, save_config=True, save_
↪function=xm.save)
```

Run the conversion script as:

```
python convert.py --checkpoint_path ckpt_29688.pt
```

After conversion, the new Hugging Face pretrained model is stored in the output directory specified by the `--output_saved_model_path` option which is `hf_saved_model` by default. You will use this directory in the next step.

To run the actual fine-tuning, create a "run_converted" file with the following script and run it:

```
export TASK_NAME=mrpc
XLA_USE_BF16=1 torchrun --nproc_per_node=2 ./run_glue.py \
--model_name_or_path hf_saved_model \
--tokenizer_name bert-large-uncased \
--task_name $TASK_NAME \
--do_train \
--do_eval \
--max_seq_length 128 \
--per_device_train_batch_size 8 \
--learning_rate 2e-5 \
--num_train_epochs 5 \
--overwrite_output_dir \
--output_dir /tmp/$TASK_NAME/ |& tee log_run_converted
```

8.6.5 Known issues and limitations

The following are currently known issues:

- Long compilation times: this can be alleviated with `neuron_parallel_compile` tool to extract graphs from a short trial run and compile them in parallel ahead of the actual run, as shown above.
- When precompiling using batch size of 16 on trn1.2xlarge, you will see `ERROR ||PARALLEL_COMPILE||: parallel compilation with neuronx-cc exited with error.Received error code: -9.` To workaround this error, please set NEURON_PARALLEL_COMPILE_MAX_RETRIES=1 in the environment.
- When running HuggingFace BERT (any size) fine-tuning tutorial or pretraining tutorial with transformers version >= 4.21.0 and using XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1, you will see NaNs in the loss

immediately at the first step. More details on the issue can be found at pytorch/xla#4152. The workaround is to use 4.20.0 or earlier or add `transformers.modeling_utils.get_parameter_dtype = lambda x: torch.bfloat16` to your Python script (i.e. run_glue.py).

- Using `neuron_parallel_compile` tool to run `run_glue.py` script with both train and evaluation options (`--do_train` and `--do_eval`), you will encounter INVALID_ARGUMENT error. To avoid this, only enable train for parallel compile (`--do_train`). This will cause compilations during evaluation step. The INVALID_ARGUMENT error will fixed in release 2.6 together with latest transformers package version 4.25.1.
- With release 2.6 and transformers==4.25.1, using `neuron_parallel_compile` tool to run `run_glue.py` script with both train and evaluation option (`--do_train` and `--do_eval`), you will encounter harmless error `ValueError: Target is multiclass but average='binary'`
- Reduced accuracy for RoBerta-Large is seen with Neuron PyTorch 1.12 (release 2.6) in FP32 mode with compiler BF16 autocast. The workaround is to set NEURON_CC_FLAGS="–auto-cast none" or set NEURON_RT_STOCHASTIC_ROUNDING_EN=1.
- Some recompilation is seen at the epoch boundary even after `neuron_parallel_compile` is used.
- When running multi-worker training, you may see the process getting killed at the time of model saving. This happens because the transformers `trainer.save_model` api uses `xm.save` for saving models. This api is known to cause high host memory usage in multi-worker setting see Saving and Loading XLA Tensors in . Coupled with a compilation at the same time results in a host OOM. To avoid this issue, we can: Precompile all the graphs in multi-worker training. This can be done by running the multi-worker training first with `neuron_parallel_compile` followed by the actual training. This would avoid the compilation at model save during actual training.

The following are currently known limitations:

- Only MRPC task fine-tuning is supported. Other tasks will be supported in the future.

This document is relevant for: `Trn1`

8.7 Megatron-LM GPT Pretraining Tutorial

GPT is a large language model that excels at many natural language processing (NLP) tasks. It is derived from the decoder part of the Transformer. Neuron Reference For Megatron-LM is a library that enables large-scale distributed training of language models such as GPT and is adapted from Megatron-LM. This tutorial explains how to run the Neuron reference for Megatron-LM GPT pretraining on Trainium.

The AWS Neuron SDK provides access to Trainium devices through an extension of PyTorch/XLA - a library that includes the familiar PyTorch interface along with XLA-specific additions. For Trainium customers, this means that existing PyTorch training scripts can be executed on Trn1 instances with minimal code modifications. For additional details relating to PyTorch/XLA, please refer to the official PyTorch/XLA documentation.

To run on Trainium, Neuron Reference For Megatron-LM library includes the following changes:

- GPU devices are replaced with Pytorch/XLA devices.
- Pytorch/XLA distributed backend is used to bridge the PyTorch distributed APIs to XLA communication semantics.
- Pytorch/XLA MpDeviceLoader is used for the data ingestion pipelines. Pytorch/XLA MpDeviceLoader helps improve performance by overlapping the three execution steps: tracing, compilation and data batch loading to the device.
- CUDA APIs are mapped to generic PyTorch APIs.

- CUDA fused optimizers are replaced with generic PyTorch alternatives.

The GPT example in this tutorial is an adaptation of the original Megatron-LM GPT example, trained using the Wikipedia dataset.

For latest performance numbers visit *Neuron Performance*

8.7.1 Install PyTorch Neuron

Before running the tutorial please follow the installation instructions at:

- *Install PyTorch Neuron on Trn1*

Please set the storage of instance to *512GB* or more if you intent to run multiple experiments and save many checkpoints.

8.7.2 Download Preprocessed Wikipedia Dataset

Download the vocabulary file, the merge table file, and the preprocessed Wikipedia dataset using the following commands:

```
export DATA_DIR=~/examples_datasets/gpt2

mkdir -p ${DATA_DIR} && cd ${DATA_DIR}

wget https://s3.amazonaws.com/models.huggingface.co/bert/gpt2-vocab.json
wget https://s3.amazonaws.com/models.huggingface.co/bert/gpt2-merges.txt
aws s3 cp s3://neuron-s3/training_datasets/gpt/wikipedia/my-gpt2_text_document.bin .  --
↪no-sign-request
aws s3 cp s3://neuron-s3/training_datasets/gpt/wikipedia/my-gpt2_text_document.idx .  --
↪no-sign-request
aws s3 cp s3://neuron-s3/training_datasets/gpt/wikipedia/license.txt .  --no-sign-request
```

See section `Preparing Wikipedia dataset from scratch` if you would like to recreate the preprocessed dataset from scratch.

8.7.3 Setting up the training environment on trn1.32xlarge

Please follow the instructions to setup Python virtual environment with Neuron packages.

Install Python3 development package needed to build the data helpers tools. If you are on Amazon Linux, do:

```
sudo yum install -y python3-devel
```

If you are on Ubuntu, do:

```
sudo apt install -y python3-dev
```

Clone the AWS Neuron Reference for Megatron-LM package, install dependencies, and build the data helpers tool:

```
cd ~/
git clone https://github.com/aws-neuron/aws-neuron-reference-for-megatron-lm.git
pip install pybind11 regex
pushd .
cd aws-neuron-reference-for-megatron-lm/megatron/data/
make
popd
```

8.7.4 GPT Pretraining Python Script

The GPT pretraining python script is a wrapper that imports the Megatron-LM library modules and sets up the pieces needed by the Megatron-LM trainer: GPT model, loss function, forward pass, data provider. It is adapted from pretrain_gpt.py. The Neuron changes are:

- Use XLA device
- Not using mpu.broadcast_data as it is currently unsupported. Instead each worker reads the data in parallel.
- Use int instead of long datatype for token data

The script is available at `~/aws-neuron-reference-for-megatron-lm/pretrain_gpt.py`

8.7.5 GPT Training Shell Script

The GPT training shell script runs the above python script with following model configurations (for 6.7 billion parameters model):

- Number of layers: 32
- Hidden size: 4096
- Number attention heads: 32
- Sequence length: 2048
- Max positional embeddings size: 2048

The following training parameters are used:

- The number of gradient accumulation microsteps is 64, with worker batch size of 1.
- The tensor parallelism degree is 8.
- The data parallelism degree is 4.
- The number of workers is 32.

Additionally, the script uses:

- CPU intitialization
- AdamW optimizer (default).
- Gradient clipping.
- No CUDA fusions (bias-gelu, masked-softmax, bias-dropout)
- Disabled contiguous buffer in local DDP
- Option `--distributed-backend xla` picks the XLA distributed backend to bridge the Pytorch distributed APIs to XLA communication semantics.

See this link for a full list of options and their descriptions.

Note: Not all options are supported. Currently only tensor-parallel and data-parallel modes in Neuron Reference For Megatron-LM are supported. We support tensor-parallel degree of 8 and data-parallel degree of upto 64.

The script for running on a single node is available at `~/aws-neuron-reference-for-megatron-lm/examples/pretrain_gpt3_6.7B_32layers_bf16.sh`

This shell script expects dataset files to be located in ~/examples_datasets/gpt2/ following the steps above. If you place the dataset files in another location, please update the DATA_PATH variable in the shell script.

8.7.6 Initiating a Training Job

To run the GPT example, first activate the Python virtual environment and change to the Megatron-LM package location:

```
source ~/aws_neuron_venv_pytorch/bin/activate
cd ~/aws-neuron-reference-for-megatron-lm/
```

Next, run the parallel compilations of graphs in order to reduce compilation time during the actual run.

```
neuron_parallel_compile sh ./examples/pretrain_gpt3_6.7B_32layers_bf16.sh
```

This command performs a short trial run of the training script to extract graphs and then do parallel compilations on those graphs before populating the persistent cache with compiled graphs. This helps reduce the compilation time during the actual run of the training script.

Note: Please ignore the results of the trial run as they are not the actual execution results.

If some or all the graphs were already compiled and cached in the persistent cache, then fewer or none of the graphs would need compilation. To force recompilation, you can remove the cache directory at `/var/tmp/neuron-compile-cache/`.

Compilation is recommended if there are some changes in the script (such as batch size, number of layers, number of workers, etc.). Compilation will only happen if the model graph or its parameters/compilation flags change.

Finally, run the script for the actual run:

```
sh ./examples/pretrain_gpt3_6.7B_32layers_bf16.sh
```

During the run, you will see outputs like below, some lines showing throughput and loss statistics every global step.

```
`iteration     4873/   10000 | consumed samples:       311872 | elapsed time per␣
↪iteration (ms): 8718.9 | learning rate: 1.500E-04 | global batch size:    64 | lm loss:
↪ 3.296875E+00 | grad norm: 0.430 | throughput: 7.340`
```

8.7.7 Monitoring Training Job Progress

Using a single Trn1 instance with 32 NeuronCores, the current GPT pretraining will run for ~81 hours. During this time, you will see the average loss metric begin at 11 and ultimately converge to ~3.2. Throughput for the training job will be ~7.3 seq/sec.

8.7.8 Monitoring Training Job Progress using neuron-top

With the training job still running, launch a second SSH connection into the trn1 instance, and use the `neuron-top` command to examine the aggregate NeuronCore utilization.

8.7.9 Monitoring Training Job Progress using TensorBoard

The demo includes TensorBoard-compatible logging, which allows the learning rate and training metrics to be monitored in real-time. By default, the training script logs metrics to the following TensorBoard log directory `~/aws-neuron-reference-for-megatron-lm/tb_*`.

In order to view your training metrics in TensorBoard, first run the following commands in your SSH session:

```
source ~/aws_neuron_venv_pytorch/bin/activate
cd ~/aws-neuron-reference-for-megatron-lm/
tensorboard --logdir ./
```

Once running, open a new SSH connection to the instance and port-forward TCP port 6006 (ex: -L 6006:127.0.0.1:6006). Once the tunnel is established, TensorBoard can then be accessed via web browser at the following URL: http://localhost:6006. Please note that you will not be able to access TensorBoard if you disconnect your port-forwarding SSH session to the Trainium instance.

8.7.10 Finishing the tutorial

Once you are ready, and the training throughput is as expected, there are a couple of options for finishing the GPT pretraining demo:

Allow the training script to run to completion. If you would like to observe the training script run to completion, it is recommended to launch the training script from a terminal multiplexer such as `tmux` or `screen`, and then detach the session so that the training script can run in the background. With this approach, you can safely let the training script run unattended, without risk of an SSH disconnection causing the training job to stop running.

Stop the training job early. To stop the training job early, press CTRL-C in the terminal window in which you launched the training script. In some cases, if you manually cancel a job using CTRL-C and then later want to run the job again, you might first need to terminate all the python processes by the command `killall -9 python3` .

8.7.11 Running a multi-node GPT

We use SLURM to launch multi-node GPT training jobs. Like single node runs, we have a precompilation step followed by the actual run. To precompile:

```
sbatch examples/pretrain_gpt3_6.7B_compile.slurm
```

This will precompile the script `examples/pretrain_gpt3_6.7B_32layers_bf16_bs1024_slurm.sh` on all the nodes and populate the caches.

To run the compiled model:

```
sbatch examples/pretrain_gpt3_6.7B.slurm
```

The number of nodes is currently set to 16 and since the tensor-parallel degree used is 8, the data-parallel degree is automatically computed to be 64, resulting in a 8x64 two dimensional mesh parallelism.

The tensorboard logs are written by the last rank and will be in the TensorBoard log directory `~/aws-neuron-reference-for-megatron-lm/tb_*`.

Compared to the single-node script, we use an increased batch size of 1024 which gives us a throughput bump of ~98 seq/sec. The number of iterations is also increased with changes in the hyperparameters pertaining to learning rates, weight decay.

8.7.12 Checkpointing GPT Model

A new mode of checkpointing using serialized tensor and staggered save/load is supported to alleviate memory pressure. To save the model, add the lines:

```
--save-xser $CHECKPOINT_PATH
--save-interval 1500
```

This will save the checkpoint at path variable provided for every 1500 iterations.

Note: Please note that the model saves all the model weights, optimizer and rng states (~76GB for a 32 layermodel). And if checkpointed frequently can quickly lead to low disk storage. Make sure there is enough disk space.

To load the checkpoint, we first need to remove `--use-cpu-initialization` from the script and then add

```
--load-xser $CHECKPOINT_PATH
```

Note: Please note not removing the –use-cpu-initialization flag may lead to out-of-memory execution and result in unstable resumption of training.

8.7.13 Preparing Wikipedia Dataset from Scratch

The process of preparing the Wikipedia dataset follows the original Megatron-LM documentation. You will need a large c5 machine like c5n.18xlarge and using the latest Deep Learning AMI. First download the Wikipedia dataset. Depending on the network bandwidth, this is expected to be about ~65 minutes.

```
export WIKI_DIR=~/examples_datasets/wiki
mkdir -p $WIKI_DIR && cd $WIKI_DIR

wget https://dumps.wikimedia.org/enwiki/latest/enwiki-latest-pages-articles.xml.bz2
```

Download the vocabulary and merge table files for the desired model. This example uses the GPT-2 model:

```
export DATA_DIR=~/examples_datasets/gpt2
export GPT2_DATA=${DATA_DIR}/gpt2

mkdir -p ${GPT2_DATA} && cd ${GPT2_DATA}

wget https://s3.amazonaws.com/models.huggingface.co/bert/gpt2-vocab.json
wget https://s3.amazonaws.com/models.huggingface.co/bert/gpt2-merges.txt

mkdir -p ${GPT2_DATA}/checkpoint
wget --content-disposition https://api.ngc.nvidia.com/v2/models/nvidia/megatron_lm_345m/
↪versions/v0.0/zip -O ${GPT2_DATA}/checkpoint/megatron_lm_345m_v0.0.zip
```

Extract the downloaded data using WikiExtractor (this step takes about 2 hours):

```
git clone https://github.com/attardi/wikiextractor.git /tmp/wikiextractor
cd /tmp/wikiextractor
python -m wikiextractor.WikiExtractor --json ~/examples_datasets/wiki/enwiki-latest-
↪pages-articles.xml.bz2 --output ~/examples_datasets/wiki/text/ -q --processes 70 2>&1␣
↪| tee wikiextract.out &
```

(continues on next page)

(continued from previous page)

The Wikiextractor first preprocesses the template of all pages sequentially, followed by a Map/Reduce process for extracting the pages and converting to the loose json format required by Megatron-LM.

Once the extraction completes, we merge the text files with (~2 minutes):

```
conda activate pytorch_latest_p37
cd ~/examples_datasets/wiki
find ~/examples_datasets/wiki/text/ -name wiki* | parallel -m -j 70 "cat {} >>␣
↪mergedfile.json"
```

The `mergedfile.json` size on disk is 16GB. With it, create the binary data format for Megatron GPT2. NOTE: Refer to this solution if an `IndexError: list index out of range` occurs. To create the binary data, type the following command:

```
python ~/aws-neuron-reference-for-megatron-lm/tools/preprocess_data.py \
    --input ~/examples_datasets/wiki/mergedfile.json \
    --output-prefix my-gpt2 \
    --vocab ~/examples_datasets/gpt2/gpt2-vocab.json \
    --dataset-impl mmap \
    --tokenizer-type GPT2BPETokenizer \
    --merge-file ~/examples_datasets/gpt2/gpt2-merges.txt \
    --append-eod \
    --workers 70
```

Files my-gpt2_text_document.* are generated after about 12 minutes.

8.7.14 Known issues and limitations

No broadcast support

Currently, the mpu.broadcast_data is unsupported on Trainium.

No pipeline parallel support

Currently, only tensor parallel and data parallel are supported and there is no pipeline parallel support in Neuron Reference For Megatron-LM.

Dropout is disabled

Currently, dropout is disabled in the example.

Error: cannot import name 'helpers' from 'megatron.data'

You may encounter the error "cannot import name 'helpers' from 'megatron.data'" like below:

```
Exception in device=NEURONT:0: cannot import name 'helpers' from 'megatron.data' (/home/
↪ec2-user/aws-neuron-reference-for-megatron-lm/megatron/data/__init__.py)

- AWS Neuron Samples for AWS ParallelCluster
- AWS Neuron Samples GitHub Repository

API Reference Guide (`torch-neuronx`)

This document is relevant for: `Trn1`

8.8 PyTorch Neuron neuron_parallel_compile CLI (`torch-neuronx`)

PyTorch Neuron performs just-in-time compilation of graphs during execution. At every step, a graph is traced. If the traced graph varies from the previous executions, it is compiled by the neuron compiler. For large models, the compilation time for each graph can be high. Moreover, because of JIT, we would compile all these graphs sequentially, hence incurring huge compilation penalty.

To reduce this compilation time during execution, the `neuron_parallel_compile` utility is provided as part of PyTorch Neuron installation. The `neuron_parallel_compile` will extract graphs from a trial run of your script, perform parallel pre-compilation of the graphs, and populate the Neuron Cache on disk with compiled graphs. Your trial run should be limited to a few steps (eg.10-15), enough for the utility to extract the different graphs needed for full execution. To run the utility:

```
neuron_parallel_compile <run commands>
```

Where `<run commands>` are the commands to run a short run (i.e. 10 steps) to trace training loops for pre-compilation. The example for the run command is `torchrun --nproc_per_node=2 <train script>`, where train script accepts `--steps_this_run` option to limit number of run steps:

```
neuron_parallel_compile torchrun --nproc_per_node=2 <train script> --steps_this_run=10
```

NOTE: To avoid hang during `neuron_parallel_compile` run, please make sure to use xm.save instead of torch.save to save checkpoints.

You may notice that the output from the model is invalid when you use `neuron_parallel_compile`. This is because, when you initiate your training run command with `neuron_parallel_compile` , the utility will run your command with certrain env variables that would put your training script into graph extraction mode. In this mode, no real execution is performed and the outputs are invalid.

Once the `neuron_parallel_compile` finishes compilation of all graphs, it will copy all the compilation results into the Neuron Cache.

Now if you run your script (without `neuron_parallel_compile`), it will be faster since the compiled graphs are already cached.

```
torchrun --nproc_per_node=2 <train script>
```

`Note`: Except for the option to limit number of run steps (such as `--steps_this_run`), the other options of `<run commands>` must match between the pre-compilation and actual run. If this is not the case, you may see additional compilations during training run because of new graphs getting generated, resulting in cache miss.

There may be additional compilations due to unreached execution paths (in case the execution path is not reached in the first few steps of graph extraction), or changes in parameters such as number of data parallel workers.

Two additional utility flags are provided:

`NEURON_PARALLEL_COMPILE_MAX_RETRIES` :

- Set the maximum number of retries when using `neuron_parallel_compile` tool. If set to N, the tool will try compilation N more time(s) if the first graph compilation failed. Example: Set NEURON_PARALLEL_COMPILE_MAX_RETRIES=1 when precompiling on trn1.2xlarge where there's limited host memory and CPU resources. Default is 0.

`NEURON_IGNORE_TRAINING_SCRIPT_ERROR_AND_COMPILE` :

- When using neuron_parallel_compile, if you want to ignore the error in training script and compile the accumulated HLO graphs, you can do so by setting this environment variable. Example: If NEURON_IGNORE_TRAINING_SCRIPT_ERROR_AND_COMPILE=1 is set when using `neuron_parallel_compile`, a crash in the training script would be ignored and the graphs collected upto the crash would be compiled.

This document is relevant for: `Trn1`

This document is relevant for: `Trn1`

8.9 PyTorch Neuron Environment Variables (torch-neuronx)

Environment variables allow modifications to PyTorch Neuron behavior without requiring code change to user script. It is recommended to set them in code or just before invoking the python process, such as NEURON_FRAMEWORK_DEBUG=1 python3 <script> to avoid inadvertently changing behavior for other scripts. Environment variables specific to PyTorch Neuron are (experimental ones are noted):

NEURON_CC_FLAGS:

- Compiler options. Full compiler options are described in the mixed-precision-casting-options. Additional options for the persistent cache can be found in the "Persistent cache" section below.

NEURON_FRAMEWORK_DEBUG **[Experimental]**:

- Enable dumping of XLA graphs in both HLO format (intermediate representation) and text form for debugging.

NEURON_EXTRACT_GRAPHS_ONLY **[Experimental]**:

- Dump the XLA graphs in HLO format (intermediate representation) and execute empty stubs with zero outputs in order to allow multiple XLA graphs to be traced through a trial execution. Used for ahead-of-time graph extraction for parallel compilation in neuron_parallel_compile tool. This environment variable can be checked in the training script to prevent checking of bad outputs during trial run.

NEURON_NUM_RECENT_MODELS_TO_KEEP **[Experimental]**:

- Keep only N number of graphs loaded in Neuron runtime for each process, where N is the value this environment variable is set to. Default is to keep all graphs loaded by a process.

NEURON_PARALLEL_COMPILE_MAX_RETRIES **[Experimental]**:

- Set the maximum number of retries when using neuron_parallel_compile tool. If set to N, the tool will try compilation N more time(s) if the first graph compilation failed. Example: Set NEURON_PARALLEL_COMPILE_MAX_RETRIES=1 when precompiling on trn1.2xlarge where there's limited host memory and CPU resources. Default is 0.

NEURON_IGNORE_TRAINING_SCRIPT_ERROR_AND_COMPILE **[Experimental]**:

- When using neuron_parallel_compile, if you want to ignore the error in training script and compile the accumulated HLO graphs, you can do so by setting this environment variable. Example: If NEURON_IGNORE_TRAINING_SCRIPT_ERROR_AND_COMPILE=1 is set when using neuron_parallel_compile, a crash in the training script would be ignored and the graphs collected upto the crash would be compiled.

NEURON_DUMP_HLO_SNAPSHOT **[Experimental]**:

- Dump the inputs, outputs, and graph in HLO format of a graph execution in a snapshot file. This variable can be set to 1, ON_NRT_ERROR, ON_NRT_ERROR_CPU, ON_NRT_ERROR_HYBRID to dump snapshots at every iteration using CPU memory, or dump only on errors automatically using device, host, and both device and host memory respectively.

NEURON_NC0_ONLY_SNAPSHOT **[Experimental]**:

- Dump only the snapshot associated with Neuron Core 0 when NEURON_NC0_ONLY_SNAPSHOT=1 and the NEURON_DUMP_HLO_SNAPSHOT flag is set.

BUCKET_CAP_MB **[PyTorch XLA]**:

- If there are many parameters, such as in BERT training, small allreduce sizes can limit performance. To improve performance, you can try increasing the bucket size using BUCKET_CAP_MB environment variable, which is set to 50MB by default. For example, BERT pretraining on multiple instances can see improved performance with BUCKET_CAP_MB=512.

XLA_USE_BF16 **[PyTorch XLA]**:

- When `XLA_USE_BF16=1`, PyTorch Neuron will automatically map both torch.float and torch.double tensors to bfloat16 tensors and turn on Stochastic Rounding mode. This can both reduce memory footprint and improve performance. Example: to enable bfloat16 autocasting and stochastic rounding, set XLA_USE_BF16=1 only, as stochastic rounding mode is on by default when XLA_USE_BF16=1. If you would like to preserve some tensors in float32, see `XLA_DOWNCAST_BF16` below.

`XLA_DOWNCAST_BF16` **[PyTorch XLA]**:

- When `XLA_DOWNCAST_BF16=1`, PyTorch Neuron will automatically map torch.float tensors to bfloat16 tensors, torch.double tensors to float32 tensors and turn on Stochastic Rounding mode. This can both reduce memory footprint and improve performance, while preserving some tensors in float32. Example: to enable float to bfloat16 and double to float autocasting and stochastic rounding, set XLA_DOWNCAST_BF16=1 only, as stochastic rounding mode is on by default when XLA_DOWNCAST_BF16=1. If you want to cast both torch.float and torch.double to bfloat16, please see `XLA_USE_BF16` above.

`NEURON_RT_STOCHASTIC_ROUNDING_EN` **[Neuron Runtime]**:

- When `NEURON_RT_STOCHASTIC_ROUNDING_EN=1`, PyTorch Neuron will use stochastic rounding instead of round-nearest-even for all internal rounding operations when casting from FP32 to a reduced precision data type (FP16, BF16, FP8, TF32). This feature has been shown to improve training convergence for reduced precision training jobs, such as when bfloat16 autocasting is enabled. This is set to 1 by default by PyTorch Neuron when XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1. To switch to round-nearest-even mode, please set `NEURON_RT_STOCHASTIC_ROUNDING_EN=0`.

`NEURON_RT_STOCHASTIC_ROUNDING_SEED` **[Neuron Runtime]**:

- Sets the seed for the random number generator used in stochastic rounding (see previous section). If this environment variable is not set, the seed is set to 0 by default. Please set `NEURON_RT_STOCHASTIC_ROUNDING_SEED` to a fixed value to ensure reproducibility between runs.

`NEURON_RT_VISIBLE_CORES` **[Neuron Runtime]**:

Integer range of specific NeuronCores needed by the process (for example, 0-3 specifies NeuronCores 0, 1, 2, and 3). You this environment variable when using torchrun to limit the launched processs to specific consecutive NeuronCores. To ensure best performance, the multi-core jobs requiring N NeuronCores for collective communication must be placed at the NeuronCore ID that starts at a multiple of N, where N is the world size limited to 1, 2, 8, 32. For example, a process using 2 NeuronCores can be mapped to 2 free NeuronCores starting at NeuronCore id 0, 2, 4, 6, etc, and a process using 8 NeuronCores can be mapped to 8 free NeuronCores starting at NeuronCore id 0, 8, 16, 24.

Additional Neuron runtime environment variables are described in runtime configuration documentation.

Additional XLA runtime environment variables are described in PyTorch-XLA troubleshooting guide.

8.10 PyTorch Neuron (`torch-neuronx`) Profiling API

The profiler provides a method to generate a context manager to capture trace events at the operator or runtime level.

`torch_neuronx.experimental.profiler.`**`profile`**(*port=9012*, *ms_duration=60000*, *neuron_tensorboard_plugin_dir='logs/plugins/neuron'*, *profile_type='operator'*, *auto_start=True*, *delete_working=True*)

The *`torch_neuronx.experimental.profiler.profile()`* method retuns a `profile` context manager object. This object doesn't need to be used directly, as default options are set to auto capture events based on the `profile_type`.

The context manager will wrap around the entire model and training/inference loop. The context-manager is backwards-compatible with the torch_xla.debug.profiler``

Required Arguments

None

Optional Keyword Arguments

Keyword Arguments

- **port** (*int*) – Port to run the profiling GRPC server on. Default is 9012.
- **ms_duration** (*int*) – This defines how long the profiler will capture the HLO artifacts from the model to view in the profiler. The unit is in milliseconds. The default value is 60000 ms, or 1 minute.
- **neuron_tensorboard_plugin_dir** (*str*) – The directory the neuron tensorboard plugin will file write to. This will be `logs/plugins/neuron` by default/
- **profile_type** (*str*) – There is "trace" and "operator". "trace" is the Torch Runtime Trace Level, while "operator" is the Model Operator Trace Level. Default is "operator"
- **auto_start** (*bool*) – If set to true, the profiler will start profiling immediately. If set to false, the profiler can be set to start at a later condition. Refer to `profile.start()` for more details. Default is `True`.
- **delete_working** (*bool*) – If set to False turns off the deletion of temporary files. Default True.

Returns The traced *profile*

Return type ~profile

`torch_neuronx.experimental.profiler.profile.start()`

The *torch_neuronx.experimental.profiler.profile.start()* method starts the profiler if not started (i.e when `auto_start=False`). This function does not take in any parameters, nor return anything.

Required Arguments

None

Optional Keyword Arguments

None

Returns None

- *Debugging and troubleshooting*

Trainium is designed to speed up model training and reduce training cost. It is available on the Trn1 instances. Each Trainium accelerator has two NeuronCores, which are the main neural network compute units.

PyTorch Neuron enables PyTorch users to train their models on Trainium's NeuronCores with little code change to their training code. It is based on the PyTorch/XLA software package.

This guide helps you get started with single-worker training and distributed training using PyTorch Neuron.

8.11.1 PyTorch Neuron

Neuron XLA device

With PyTorch Neuron the default XLA device is mapped to a NeuronCore. By default, one NeuronCore is configured. To use Neuron XLA device, specify the device as `xm.xla_device()` or `'xla'`:

```
import torch_xla.core.xla_model as xm
device = xm.xla_device()
```

or

```
device = 'xla'
```

PyTorch models and tensors can be mapped to the device as usual:

```
model.to(device)
tensor.to(device)
```

To move tensor back to CPU, do :

```
tensor.cpu()
```

or

```
tensor.to('cpu')
```

8.11.2 PyTorch Neuron single-worker training quick-start

PyTorch Neuron uses XLA to enable conversion of PyTorch operations to Trainium instructions. To get started on PyTorch Neuron, first modify your *training script* to use XLA in the same manner as described in PyTorch/XLA documentation and use XLA device:

```
import torch_xla.core.xla_model as xm

device = xm.xla_device()
# or
device = 'xla'
```

The NeuronCore is mapped to an XLA device. On Trainium instance, the XLA device is automatically mapped to the first available NeuronCore.

By default the above steps will enable the training script to run on one NeuronCore. NOTE: Each process is mapped to one NeuronCore.

Finally, add `mark_step` at the end of the training step to compile and execute the training step:

```
xm.mark_step()
```

These changes can be placed in control-flows in order to keep the script the same between PyTorch Neuron and CPU/GPU. For example, you can use an environment variable to disable XLA which would cause the script to run in PyTorch native mode (using CPU on Trainium instances and GPU on GPU instances):

```
device = 'cpu'
if not os.environ.get("DISABLE_XLA", None):
    device = 'xla'

...

    # end of training step
    if not os.environ.get("DISABLE_XLA", None):
        xm.mark_step()
```

More on the need for mark_step is at *Understand the lazy mode in PyTorch Neuron*.

For a full runnable example, please see the Single-worker MLP training on Trainium tutorial.

8.11.3 PyTorch Neuron multi-worker data parallel training using torchrun

Data parallel training allows you to replicate your script across multiple workers, each worker processing a proportional portion of the dataset, in order to train faster.

To run multiple workers in data parallel configuration, with each worker using one NeuronCore, first add additional imports for parallel dataloader and multi-processing utilities:

```
import torch_xla.distributed.parallel_loader as pl
```

Next we initialize the Neuron distributed context using the XLA backend for torch.distributed:

```
import torch_xla.distributed.xla_backend
torch.distributed.init_process_group('xla')
```

Next, replace `optimizer.step()` function call with `xm.optimizer_step(optimizer)` which adds gradient synchronization across workers before taking the optimizer step:

```
xm.optimizer_step(optimizer)
```

If you're using a distributed dataloader, wrap your dataloader in the PyTorch/XLA's `MpDeviceLoader` class which provides buffering to hide CPU to device data load latency:

```
parallel_loader = pl.MpDeviceLoader(dataloader, device)
```

Within the training code, use xm.xrt_world_size() to get the world size, and xm.get_ordinal to get the global rank of the current process.

Then run use PyTorch torchrun utility to run the script. For example, to run 32 worker data parallel training:

```
torchrun --nproc_per_node=32 <script and options>
```

To run on multiple instances, make sure to use trn1.32xlarge instances and use all 32 NeuronCores on each instance. For example, with two instances, on the rank-0 Trn1 host, run with –node_rank=0 using torchrun utility:

```
torchrun --nproc_per_node=32 --nnodes=2 --node_rank=0 --master_addr=<root IP> --master_
↪port=<root port> <script and options>
```

On another Trn1 host, run with –node_rank=1 :

```
torchrun --nproc_per_node=32 --nnodes=2 --node_rank=1 --master_addr=<root IP> --master_
↪port=<root port> <script and options>
```

It is important to launch rank-0 worker with –node_rank=0 to avoid hang.

More information about torchrun can be found PyTorch documentation at https://pytorch.org/docs/stable/elastic/run.html#launcher-api .

See the Multi-worker data-parallel MLP training using torchrun tutorial for a full example.

8.11.4 Conversion from Distributed Data Parallel (DDP) application

Distributed Data Parallel (DDP) in torch.distributed module is a wrapper to help convert a single-worker training to distributed training. To convert from torch.distributed Distributed Data Parallel (DDP) application to PyTorch Neuron, first convert the application back to single-worker training, which simply involves removing the DDP wrapper, for example `model = DDP(model, device_ids=[rank])`. After this, follow the previous section to change to multi-worker training.

8.11.5 PyTorch Neuron environment variables

Environment variables allow modifications to PyTorch Neuron behavior without requiring code change to user script. See *PyTorch Neuron environment variables* for more details.

8.11.6 Persistent cache for compiled graphs

PyTorch/XLA has an internal in-memory compilation cache that caches previously compiled graphs within the same python process. However this internal cache is not persistent between runs. PyTorch Neuron includes a persistent cache that enables caching of previously compiled graph on disk so that subsequent run of the same program do not incur long compilation time. This cache is enabled by default and the default cache directory is /var/tmp/neuron-compile-cache.

The cache uses hash of the Neuron compiler flags and XLA graph as the key. If the Neuron compiler version or XLA graph changes, you will see recompilation. Examples of changes that would cause XLA graph change include:

- Model type and size
- Batch size
- Optimizer and optimizer hyperparameters
- Location of xm.mark_step()

To disable the cache, you can pass `--no_cache` option via NEURON_CC_FLAGS:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --no_cache'
```

To change the cache's root directory, pass `cache_dir=<root dir>` option via NEURON_CC_FLAGS (the actual cache directory will be in `<root dir>/neuron-compile-cache`:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --cache_dir=
↪<root dir>'
```

Stale cached compiled graphs (NEFFs) are deleted from the cache whenever the size of cache is above default cache size of 100GB . The deletion order is based on least-recently-used first. To change the cache size, pass `--cache_size=SIZE_IN_BYTES`. For example, to change the cache size to 16 MB:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --cache_
↪size=16777216'
```

A cache entry considered stale if the last used time is older than a time-to-live value, currently default to 30 days. If the last used time is earlier than the time-to-live value, then it is not deleted even if cache size exceeds cache size limit. To change cache time-to-live, set the option `--cache_ttl` to the number of days desired:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --cache_ttl=60'
```

If in some cases, the compilation failed because of an environment issue, and you want to retry compilation, you can do so by adding `--retry_failed_compilation`. This will retry the compilation even if there is a failed NEFF in the cache.

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --retry_failed_
↪compilation'
```

You can change the verbose level of the compiler by adding `log_level` to either `WARNING`, `INFO` or `ERROR`. This can be done as follows:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --log_
↪level=INFO'
```

8.11.7 Number of graphs

PyTorch/XLA converts PyTorch's eager mode execution to lazy-mode graph-based execution. During this process, there can be multiple graphs compiled and executed if there are extra mark-steps or functions with implicit mark-steps. Additionally, more graphs can be generated if there are different execution paths taken due to control-flows.

8.11.8 Automatic casting of float tensors to BFloat16

With PyTorch Neuron, the default behavior is for torch.float (FP32) and torch.double (FP64) tensors to be mapped to torch.float in hardware. To reduce memory footprint and improve performance, torch.float and torch.double tensors can automatically be converted to BFloat16 by setting the environment variable `XLA_USE_BF16=1`. Alternatively, torch.float can automatically be converted to BFloat16 and torch.double converted to FP32 by setting the environment variable `XLA_DOWNCAST_BF16=1`.

8.11.9 Automatic Mixed-Precision

BF16 mixed-precision using PyTorch Autocast

By default, the compiler automatically cast internal FP32 operations to BF16. You can disable this and allow PyTorch's BF16 mixed-precision to do the casting. PyTorch's BF16 mixed-precision is achieved by casting certain operations to operate BF16. We currently use CUDA's list of operations that can operate in BF16:

(NOTE: Although convolution is in the list below, it is currently unsupported by Neuron. See model-architecture-fit)

```
_convolution
_convolution
_convolution_nogroup
conv1d
conv2d
conv3d
conv_tbc
conv_transpose1d
```

(continues on next page)

(continued from previous page)

```
conv_transpose2d
conv_transpose3d
convolution
cudnn_convolution
cudnn_convolution_transpose
cudnn_convolution
cudnn_convolution_transpose
cudnn_convolution
cudnn_convolution_transpose
prelu
addmm
addmv
addr
matmul
mm
mv
linear
addbmm
baddbmm
bmm
chain_matmul
linalg_multi_dot
```

To enable PyTorch's BF16 mixed-precision, first turn off the Neuron compiler auto-cast:

```
os.environ["NEURON_CC_FLAGS"] = "--auto-cast=none"
```

Next, overwrite torch.cuda.is_bf16_supported to return True:

```
torch.cuda.is_bf16_supported = lambda: True
```

Next, per recommendation from official PyTorch documentation, place only the forward-pass of the training step in the torch.autocast scope:

```
with torch.autocast(dtype=torch.bfloat16, device_type='cuda'):
    # forward pass
```

The device type is CUDA because we are using CUDA's list of BF16 compatible operations as mentioned above.

Example showing the original training code snippet:

```
def train_loop_fn(train_loader):
    for i, data in enumerate(train_loader):
        inputs = data[0]
        labels = data[3]
        outputs = model(inputs, labels=labels)
        loss = outputs.loss/ flags.grad_acc_steps
        loss.backward()
        optimizer.step()
        xm.mark_step()
```

The following shows the training loop modified to use BF16 autocast:

```
os.environ["NEURON_CC_FLAGS"] = "--auto-cast=none"

def train_loop_fn(train_loader):
    for i, data in enumerate(train_loader):
        torch.cuda.is_bf16_supported = lambda: True
        with torch.autocast(dtype=torch.bfloat16, device_type='cuda'):
            inputs = data[0]
            labels = data[3]
            outputs = model(inputs, labels=labels)
        loss = outputs.loss/ flags.grad_acc_steps
        loss.backward()
        optimizer.step()
        xm.mark_step()
```

For a full example of BF16 mixed-precision, see *PyTorch Neuron BERT Pretraining Tutorial*.

See official PyTorch documentation for more details about torch.autocast .

8.11.10 Tips and Best Practices

Understand the lazy mode in PyTorch Neuron

One significant difference between PyTorch Neuron and native PyTorch is that the PyTorch Neuron system runs in lazy mode while the native PyTorch runs in eager mode. Tensors in lazy mode are placeholders for building the computational graph until they are materialized after the compilation and evaluation are complete. The PyTorch Neuron system builds the computational graph on the fly when you call PyTorch APIs to build the computation using tensors and operators. The computational graph gets compiled and executed when `xm.mark_step()` is called explicitly or implicitly by `pl.MpDeviceLoader/pl.ParallelLoader`, or when you explicitly request the value of a tensor such as by calling `loss.item()` or `print(loss)`.

Minimize the number of compilation-and-executions

For best performance, you should keep in mind the possible ways to initiate compilation-and-executions as described in *Understand the lazy mode in PyTorch/XLA* and should try to minimize the number of compilation-and-executions. Ideally, only one compilation-and-execution is necessary per training iteration and is initiated automatically by `pl.MpDeviceLoader/pl.ParallelLoader`. The `MpDeviceLoader` is optimized for XLA and should always be used if possible for best performance. During training, you might want to examine some intermediate results such as loss values. In such case, the printing of lazy tensors should be wrapped using `xm.add_step_closure()` to avoid unnecessary compilation-and-executions.

Ensure common initial weights across workers

To achieve best accuracy during data parallel training, all workers need to have the same initial parameter states. This can be achieved by using the same seed across the workers. In the case of HuggingFace library, the set_seed function can be used. (https://github.com/pytorch/xla/issues/3216).

Use PyTorch/XLA's model save function

To avoid problems with saving and loading checkpoints, make sure you use PyTorch/XLA's model save function to properly checkpoint your model. For more information about the function, see torch_xla.core.xla_model.save in the *PyTorch on XLA Devices* documentation.

When training using multiple devices, `xla_model.save` can result in high host memory usage. If you see such high usage causing the host to run out of memory, please use torch_xla.utils.serialization.save . This would save the model in a serialized manner. When saved using the `serialization.save` api, the model should be loaded using `serialization.load` api. More information on this here: Saving and Loading Tensors

8.11.11 FAQ

What is the difference between Trainium and Inferentia?

Trainium is an accelerator designed to speed up training, whereas Inferentia is an accelerator designed to speed up inference.

8.11.12 Debugging and troubleshooting

To debug on PyTorch Neuron, please follow the debug guide.

8.12 How to debug models in PyTorch Neuron (`torch-neuronx`)

Table of Contents

- *Printing Metrics*
- *Printing Tensors*
- *Use mark_step*
- *Using Eager Debug Mode*
- *Profiling Model Run*
- *Snapshotting*
  - *Snapshot FAQs:*

Torch-XLA evaluates operations lazily, which means it builds a symbolic graph in the background and the graph is executed in hardware only when the users request (print) for the output or a mark_step is encountered. To effectively debug training scripts with torch-xla, please use one of the approaches mentioned below:

8.12.1 Printing Metrics

Torch-xla provides a utility that records metrics of different sections of the code. These metrics can help figure out things like: How much time is spent in compilation? How much time is spent in execution? To check the metrics:

1. Import metrics: `import torch_xla.debug.metrics as met`
2. Print metrics at the end of the step: `print(met.metrics_report())`

Printing metrics should produce an output that looks like this:

```
Metric: CompileTime
  TotalSamples: 1
  Accumulator: 09s969ms486.408us
  Percentiles: 1%=09s969ms486.408us; 5%=09s969ms486.408us; 10%=09s969ms486.408us; 20
↪%=09s969ms486.408us; 50%=09s969ms486.408us; 80%=09s969ms486.408us; 90%=09s969ms486.

```

As seen, you can get useful information about graph compile times/execution times. You can also know which operators are present in the graph, which operators are run on the CPU and which operators are run on an XLA device. For example, operators that have a prefix `aten::` would run on the CPU, since they do not have xla lowering. All operators with prefix `xla::` would run on an XLA device. Note: aten operators that do not have xla lowering would result in a graph fragmentation and might end up slowing down the entire execution. If you encounter such operators, create a request for operator support.

8.12.2 Printing Tensors

Users can print tensors in their script as below:

```
import os
import torch
import torch_xla
import torch_xla.core.xla_model as xm

device = xm.xla_device()
input1 = torch.randn(2,10).to(device)
# Defining 2 linear layers
linear1 = torch.nn.Linear(10,30).to(device)
```

(continues on next page)

(continued from previous page)

```
linear2 = torch.nn.Linear(30,20).to(device)

# Running forward
output1 = linear1(input1)
output2 = linear2(output1)
print(output2)
```

Since torch-xla evaluates operations lazily, when you try to print `output2` , the graph associated with the tensor would be evaluated. When a graph is evaluated, it is first compiled for the device and executed on the selected device. Note: Each tensor would have a graph associated with it and can result in graph compilations and executions. For example, in the above script, if you try to print `output1` , a new graph is cut and you would see another evaluation. To avoid multiple evaluations, you can make use of `mark_step` (next section).

8.12.3 Use mark_step

Torch-XLA provides an api called `mark_step` which evaluates a graph collected upto that point. While this is similar to printing of an output tensor wherein a graph is also evaluated, there is a difference. When an output tensor is printed, only the graph associated with that specific tensor is evaluated, whereas mark_step enables all the output tensors up to `mark_step` call to be evaluated in a single graph. Hence, any tensor print after `mark_step` would be effectively free of cost as the tensor values are already evaluated. Consider the example below:

```
import os
import torch
import torch_xla
import torch_xla.core.xla_model as xm
import torch_xla.debug.metrics as met

device = xm.xla_device()
input1 = torch.randn(2,10).to(device)
# Defining 2 linear layers
linear1 = torch.nn.Linear(10,30).to(device)
linear2 = torch.nn.Linear(30,20).to(device)

# Running forward
output1 = linear1(input1)
output2 = linear2(output1)
xm.mark_step()
print(output2)
print(output1)
# Printing the metrics to check if compilation and execution occurred
print(met.metrics_report())
```

In the printed metrics, the number of compiles and executions is only 1, even though 2 tensors are printed. Hence, to avoid multiple graph evaluations, it is recommended that you visualize tensors after a `mark_step` . You can also make use of the add_step_closure api for this purpose. With this api, you pass in the tensors that needs to be visualized/printed. The added tensors would then be preserved in the graph and can be printed as part of the callback function passed to the api. Here is a sample usage: https://github.com/pytorch/xla/blob/master/test/test_train_mp_mnist.py#L133

Note: Graph compilations can take time as the compiler optimizes the graph to run on device.

8.12.4 Using Eager Debug Mode

Eager debug mode provides a convenient utility to step through the code and evaluate operators one by one for correctness. Eager debug mode is useful to inspect your models the way you would do in eager-mode frameworks like PyTorch and Tensorflow. With Eager Debug Mode operations are executed eagerly. As soon as an operation is registered with torch-xla, it would be sent for compilation and execution. Since compiling a single operation, the time spent would be minimal. Moreover, the chances of hitting the framework compilation cache increases as models would have repeated operations throughout. Consider example 1 below:

```
# Example 1

import os
# You need to set this env variable before importing torch-xla
# to run in eager debug mode.
os.environ["NEURON_USE_EAGER_DEBUG_MODE"] = "1"

import torch
import torch_xla
import torch_xla.core.xla_model as xm
import torch_xla.debug.metrics as met

device = xm.xla_device()
input1 = torch.randn(2,10).to(device)
# Defining 2 linear layers
linear1 = torch.nn.Linear(10,30).to(device)
linear2 = torch.nn.Linear(30,20).to(device)

# Running forward
output1 = linear1(input1)
output2 = linear2(output1)

# Printing the metrics to check if compilation and execution occurred
# Here, in the metrics you should notice that the XRTCompile and XRTExecute
# value is non-zero, even though no tensor is printed. This is because, each
# operation is executed eagerly.
print(met.metrics_report())

print(output2)
print(output1)
# Printing the metrics to check if compilation and execution occurred.
# Here the XRTCompile count should be same as the previous count.
# In other words, printing tensors did not incur any extra compile
# and execution of the graph
print(met.metrics_report())
```

As seen from the above scripts, each operator is evaluated eagerly and there is no extra compilation when output tensors are printed. Moreover, together with the on-disk Neuron persistent cache, eager debug mode only incurs one time compilation cost when the ops is first run. When the script is run again, the compiled ops will be pulled from the persistent cache. Any changes you make to the training script would result in the re-compilation of only the newly inserted operations. This is because each operation is compiled independently. Consider example 2 below:

```
# Example 2

import os
```

(continues on next page)

(continued from previous page)

```
# You need to set this env variable before importing torch-xla
# to run in eager debug mode.
os.environ["NEURON_USE_EAGER_DEBUG_MODE"] = "1"

import torch
import torch_xla
import torch_xla.core.xla_model as xm
import torch_xla.debug.metrics as met

os.environ['NEURON_CC_FLAGS'] = "--log_level=INFO"

device = xm.xla_device()
input1 = torch.randn(2,10).to(device)
# Defining 2 linear layers
linear1 = torch.nn.Linear(10,30).to(device)
linear2 = torch.nn.Linear(30,20).to(device)
linear3 = torch.nn.Linear(20,30).to(device)
linear4 = torch.nn.Linear(30,20).to(device)

# Running forward
output1 = linear1(input1)
output2 = linear2(output1)
output3 = linear3(output2)

# Note the number of compiles at this point and compare
# with the compiles in the next metrics print
print(met.metrics_report())

output4 = linear4(output3)
print(met.metrics_report())
```

Running the above example 2 script after running example 1 script, you may notice that from the start until the statement `output2 = linear2(output1)` , all the graphs would hit the persistent cache. Executing the line `output3 = linear3(output2)` would result in a new compilation for `linear3` layer only because the layer configuration is new. Now, when we run `output4 = linear4(output3)` , you would observe no new compilation happens. This is because the graph for `linear4` is same as the graph for `linear2` and hence the compiled graph for `linear2` is reused for `linear4` by the framework's internal cache.

Eager debug mode avoids the wait times involved with tensor printing because of larger graph compilation. It is designed only for debugging purposes, so when the training script is ready, please remove the `NEURON_USE_EAGER_DEBUG_MODE` environment variable from the script in order to obtain optimal performance.

By default, in eager debug mode the logging level in the Neuron compiler is set to error mode. Hence, no logs would be generated unless there is an error. Before your first print, if there are many operations that needs to be compiled, there might be a small delay. In case you want to check the logs, switch on the `INFO` logs for compiler using:

```
os.environ["NEURON_CC_FLAGS"] = "--log_level=INFO"
```

8.12.5 Profiling Model Run

Profiling model run can help to identify different bottlenecks and resolve issues faster. You can profile different sections of the code to see which block is the slowest. To profile model run, you can follow the steps below:

1. Add: `import torch_xla.debug.profiler as xp`
2. Start server. This can be done by adding the following line after creating xla device: `server = xp.start_server(9012)`
3. In a separate terminal, start tensorboard. The logdir should be in the same directory from which you run the script.

   Open the tensorboard on a browser. Go to profile section in the top right. Note: you may have to install the profile plugin using: `pip install tensorboard-plugin-profile`

4. When you click on the profile, it should give an option to capture profile. Clicking on capture profile produces the following pop-up.

In the URL enter: `localhost:9012` . Port in this URL should be same as the one you gave when starting the server in the script.

5. Once done, click capture and it should automatically load the following page:

6. To check the profile for different blocks of code, head to `trace_viewer` under `Tools` (on the left column).

7. It should show a profile that looks like this:

Note: By default, torch-xla would time different blocks of code inside the library. However, you can also profile block of code in your scripts. This can be done by adding the code within a `xp.Trace` context as follows:

```
....
for epoch in range(total_epochs):
    inputs = torch.randn(1,10).to(device)
    labels = torch.tensor([1]).to(device)
    with xp.Trace("model_build"):
        loss = model(inputs, labels)
```

(continues on next page)

(continued from previous page)

```
    with xp.Trace("loss_backward"):
        loss.backward()
....
```

It should produce a profile that has the `model_build` and `loss_backward` section timed. This way you can time any block of script for debugging.

Note: If you are running your training script in a docker container, to view the tensorboard, you should launch the docker container using flag: `--network host` eg. `docker run --network host my_image:my_tag`

8.12.6 Snapshotting

Snapshotting models can be used to dump debug information that can then be sent to the Neuron team. Neuron execution relies on a series of compiled graphs. Internally, graph HLOs are used as an intermediate representation which is then compiled. Then, during execution, the graph inputs are passed to the Neuron runtime, which produces outputs using the compiled graph. Snapshotting saves the inputs to a graph execution, executes the graphs, saves the outputs of the execution, and then bundles and dumps the inputs, outputs and graph HLO in one file. This is illustrated here:

This feature can be enabled using the following environment variables, which can be set at the beginning of your script as follows.

```
....
os.environ["XLA_FLAGS"] = " --xla_dump_to=dump"
os.environ["NEURON_FRAMEWORK_DEBUG"] = "1"
os.environ["NEURON_DUMP_HLO_SNAPSHOT"] = "1"
....
```

This set of environment variables will produce snapshots under the dump folder with the extensions `.hlo.snapshot.pb` or `.decomposed_hlo_snapshot` at every iteration. For example a file that looks like the following would be produced.

```
dump/module_SyncTensorsGraph.387.pid_12643.execution_7496.hlo_snapshot.pb
```

The dumping environment variable can be set and unset at specific iterations as shown in the following example.

```
....
for step in range(STEPS):
    if step == 20:
        os.environ["NEURON_DUMP_HLO_SNAPSHOT"] = "1"
    else:
        os.environ.pop('NEURON_DUMP_HLO_SNAPSHOT', None)
    train_x = torch.randn(BATCH_SIZE, 28, 28)
    train_x = train_x.to(device)
    loss = model(train_x)
    loss.backward()
    optimizer.step()
    xm.mark_step()
....
```

Additionally, we provide capabilities to snapshot graphs automatically. The environment variables above can be set as follows:

```
....
os.environ["XLA_FLAGS"] = " --xla_dump_to=dump"
os.environ["NEURON_FRAMEWORK_DEBUG"] = "1"
os.environ["NEURON_DUMP_HLO_SNAPSHOT"] = "ON_NRT_ERROR"
....
```

When unexpected errors such as a graph execution producing NaNs occurs, snapshots will be automatically produced and execution will be terminated. Occasionally, for larger models, automatic snapshotting may not capture snapshots due to the device memory being exhausted. In this case, the above flag can be set to `os.environ["NEURON_DUMP_HLO_SNAPSHOT"] = "ON_NRT_ERROR_HYBRID"`, this will allocate memory for inputs on both the device and host memory. In some additional cases, this may still go out of memory and may need to be set to `os.environ["NEURON_DUMP_HLO_SNAPSHOT"] = "ON_NRT_ERROR_CPU"` to avoid allocating any memory on the device at all for automatic snapshotting.

Snapshot FAQs:

When should I use this features?

This feature should be used when debugging errors that requires interfacing with and providing debug data to the Neuron team. Snapshotting may be redundant and unnecessary in some situations. For example, when only the model weights are necessary for debugging, methods such as checkpointing may be more convenient to use.

What sort of data is captured with these snapshots?

The type of data captured by these snapshots may include model graphs in HLO form, weights/parameters, optimizer states, intermediate tensors and gradients. This data may be considered sensitive and this should be taken into account before sending the data to the Neuron team.

What is the size of these snapshots?

The size of snapshots can be significant for larger models such as GPT or BERT with several GBs worth of data for larger graphs, so it is recommended to check that sufficient disk space exists before using snapshotting. In addition, limiting the amount of snapshots taken in a run will help to preserve disk space.

Will snapshotting add overhead to my execution?

Snapshotting does add a small overhead to the execution in most cases. This overhead can be significant if snapshots are dumped at every iteration. In order to alleviate some of this overhead, in the case that snapshotting is not necessary on all cores the following environment variable can be set to collect snapshots only on the first core. In addition, checkpointing in tandem with snapshotting can be useful to reduce overhead. A checkpoint close to the problem iteration can be captured, then execution resumed with snapshots enabled.

```
....
os.environ["NEURON_NC0_ONLY_SNAPSHOT"] = "1"
....
```

How can I share snapshots with the Neuron team?

These snapshots can be shared with the Neuron team via S3 bucket.

8.13 Developer Guide for Profiling with PyTorch Neuron (torch-neuronx)

Table of Contents

- *Introduction*
- *Example used in this guide*
  - *Prerequisites*
  - *Environment*
  - *Setup*
- *Viewing the Trace on TensorBoard*
- *Using Named Blocks for the Trace*

8.13.1 Introduction

The Neuron PyTorch profiler is a context manager wrapping around the entire model and training loop. Specifically this is the context manager: `torch_neuronx.experimental.profiler.profile`. This is a wrapper of the XLA Debug Profiler which we imported earlier as `import torch_xla.debug.profiler as xp`, and is backwards-compatible. Here are the parameters of the profiler context manager:

1. `port`: Port to run the profiling GRPC server on. Default is 9012.
2. `profile_type`: There is "trace" and "operator". "trace" is the Torch Runtime Trace Level, while "operator" is the Model Operator Trace Level.
3. `ms_duration`: This defines how long the profiler will capture the HLO artifacts from the model to view in the profiler. The unit is in milliseconds.
4. `neuron_tensorboard_plugin_dir`: The directory the neuron tensorboard plugin will file write to (NB: Assumes that the tensorboard logdir="log/")
5. `delete_working`: If set to False turns off the deletion of temporary files (default True)

We move the model to the xla device *inside the context manager.* This is important, as this allows the profiler to collect the operations and processes from the `neuronx-cc` compiler artifacts. If the model is moved to the xla device outside of the context manager, the profiling won't work.

Note: The warnings about the `XLA_IR_DEBUG` and `XLA_HLO_DEBUG` env vars not being set can be ignored for the most part. This warning only comes into play when compiling the model for Neuron outside of the profiler context manager.

After running this script, notice a `./logs` directory has been created. It contains the TensorBoard logs including the profiler views.

8.13.2 Example used in this guide

We will use the following code sample to describe in detail how to use the Neuron PyTorch profiling API.

Prerequisites

1. Initial Trn1 setup for PyTorch (torch-neuronx) has been done

Environment

```
#activate python virtual environment and install tensorboard_plugin_neuron
source ~/aws_neuron_venv_pytorch_p38/bin/activate
pip install tensorboard_plugin_neuronx

#create work directory for the Neuron Profiling tutorials
mkdir -p ~/neuron_profiling_tensorboard_examples
cd ~/neuron_profiling_tensorboard_examples
```

Setup

Create a new working directory:

```
mkdir simple_demo
cd simple_demo
```

Save the following code as `demo.py`:

```
import os

import torch
import torch.nn as nn
import torch.nn.functional as F

# XLA imports
import torch_xla
import torch_xla.core.xla_model as xm
import torch_xla.debug.profiler as xp

import torch_neuronx
from torch_neuronx.experimental import profiler

os.environ["NEURON_CC_FLAGS"] = "--cache_dir=./compiler_cache"

# Global constants
EPOCHS = 10

# Declare 3-layer MLP Model
class MLP(nn.Module):
  def __init__(self, input_size = 10, output_size = 2, layers = [5, 5]):
      super(MLP, self).__init__()
      self.fc1 = nn.Linear(input_size, layers[0])
```

(continues on next page)

(continued from previous page)

```
        self.fc2 = nn.Linear(layers[0], layers[1])
        self.fc3 = nn.Linear(layers[1], output_size)

    def forward(self, x):
        x = F.relu(self.fc1(x))
        x = F.relu(self.fc2(x))
        x = self.fc3(x)
        return F.log_softmax(x, dim=1)

def main():
    # Fix the random number generator seeds for reproducibility
    torch.manual_seed(0)

    # XLA: Specify XLA device (defaults to a NeuronCore on Trn1 instance)
    device = xm.xla_device()

    # Start the proflier context-manager
    with torch_neuronx.experimental.profiler.profile(
        port=9012,
        profile_type='trace',
        ms_duration=15000 ) as profiler:

        # IMPORTANT: the model has to be transferred to XLA within
        # the context manager, otherwise profiling won't work
        model = MLP().to(device)
        optimizer = torch.optim.SGD(model.parameters(), lr=0.01)
        loss_fn = torch.nn.NLLLoss()

        # start training loop
        print('----------Training ---------------')
        model.train()
        for epoch in range(EPOCHS):
            optimizer.zero_grad()
            train_x = torch.randn(1,10).to(device)
            train_label = torch.tensor([1]).to(device)

            #forward
            loss = loss_fn(model(train_x), train_label)

            #back
            loss.backward()
            optimizer.step()

            # XLA: collect ops and run them in XLA runtime
            xm.mark_step()

    print('----------End Training ---------------')

if __name__ == '__main__':
    main()
```

Then run it!

```
python demo.py
```

8.13.3 Viewing the Trace on TensorBoard

To view the TensorBoard logs, run `tensorboard --logdir=./logs`

Note: Depending on TensorBoard version `--load_fast=false` might be an additional parameter to add to view the trace.

Take note of the port (usually 6006) and enter `localhost:<port>` into the local browser (assuming port forwarding is set up properly):

```
TensorBoard 1.15.0 at http://ip-172-31-33-242:6006/ (Press CTRL+C to quit)
```

Once `localhost:<port>` is entered, verify that the "NEURON" view is shown:

If "NEURON" isn't shown on the top left hand side, select "NEURON" from the drop down on the top right hand side

On the Left Hand Side, there are two dropdown menus: Run & Tool.

The Run dropdown would contain the Torch Runtime Trace and Operator Level Trace views; however since we only ran the "trace" (i.e Torch Runtime Trace Level), we'll only see that log. The Torch Runtime Trace views are simply dates in `year_month_day_hour_minute_second_millisecond` format. The Tool Dropdown only contains the "trace" option.

The trace view should look like this:

Let's zoom into the following section of the trace:

After zooming in the trace should look like this:

Notice on the top, there is a `StepMarker` process followed by `NeuronDevice Execution` process. This correlates to the `xm.mark_step()` call which executes the collected graph of our model on Neuron. For the Operator Level Trace ("operator"), we'll be profiling the model operators that occur on Neuron. In other words, the profiler will zoom into the `NeuronDevice Execution` process, if the user specifies `profile_type='trace'`.

8.13.4 Using Named Blocks for the Trace

What we've produced so far is the default behavior of the profiler, however it would be more useful to profile specific blocks of our code to narrow down onto performance bottlenecks. To do this, use `xp.Trace` context manager. Replace the respective code in the training loop with the following:

```
...
optimizer.zero_grad()
train_x = torch.randn(1,10).to(device)
train_label = torch.tensor([1]).to(device)

with xp.Trace("model_build"):
    loss = loss_fn(model(train_x), train_label)
with xp.Trace("loss_backward"):
    loss.backward()
with xp.Trace("optimizer_step"):
    optimizer.step()

# XLA: collect ops and run them in XLA runtime
xm.mark_step()
...
```

Run the script, and follow the same TensorBoard steps. Afterwards, the trace should look like this:

As seen, the `model_build`, `loss_backward` and `optimizer_step` sections have been profiled.

Note: If you are running your training script in a docker container, to view the tensorboard, you should launch the

docker container using flag: `-network host` eg. `docker run -network host my_image:my_tag`

8.14 PyTorch Neuron (`torch-neuronx`) - Training Supported Operators

Table of Contents

- *Operator support*

8.14.1 Operator support

The following list the aten operators supported by torch-neuronx.

aten::_s_where
aten::_softmax
aten::_softmax_backward_data
aten::_unsafe_view
aten::add
aten::addcdiv_
aten::addcmul
aten::addmm
aten::bernoulli_
aten::bmm
aten::constant_pad_nd
aten::div
aten::embedding
aten::embedding_dense_backward
aten::empty
aten::expand
aten::fill_
aten::index_select
aten::_log_softmax
aten::_log_softmax_backward_data
aten::lt
aten::mm
aten::mul
aten::native_batch_norm
aten::native_batch_norm_backward
aten::neg
aten::permute
aten::relu
aten::rsub
aten::select
aten::slice

continues on next page

Table 1 – continued from previous page

aten::sqrt
aten::sum
aten::t
aten::tanh
aten::tanh_backward
aten::threshold_backward
aten::transpose
aten::unsqueeze
aten::view
aten::zero_

8.15 PyTorch Neuron (`torch-neuronx`) for Training Troubleshooting Guide

Table of contents

- *General Troubleshooting*
- *Possible Error Conditions*
  - *Non-Fatal Error OpKernel ('op: "TPU*" device_type: "CPU"')*
  - *XLA runtime error: "Invalid argument: Cannot assign a device for operation"*
  - *Error: "Could not start gRPC server"*
  - *Failed compilation result in the cache*
  - *Compilation error: "Expect ap datatype to be of type float32 float16 bfloat16 uint8"*
  - *NeuronCore(s) not available - Requested:1 Available:0*
  - *TDRV error "TDRV:exec_consume_infer_status_notification"*
  - *TDRV error "TDRV:tdrv_one_tmpbuf_reserve Number of ONE TMPBUF pages requested exceeded the max number of pages allowed (requested: <N>, max allowed: 16)."*
  - *Could not open the ndX, close device failed, TDRV not initialized*
  - *Multiworker execution hangs during NCCL init*
  - *NRT init error "One or more engines are running. Please restart device by reloading driver"*
  - *NRT error "ERROR TDRV:kbl_model_add Attempting to load an incompatible model!"*
  - *NRT error "ERROR HAL:aws_hal_sprot_config_remap_entry SPROT remap destination address must be aligned size"*
  - *NCCL warning : "NCCL WARN Timeout waiting for RX (waited 120 sec) - retrying"*
  - *RPC error: "RPC failed with status = 'UNAVAILABLE: Socket closed'"*
  - *Error "Assertion `listp->slotinfo[cnt].gen <= GL(dl_tls_generation)' failed" followed by 'RPC failed with status = "UNAVAILABLE: Connection reset by peer"'*

- *RPC connection error: "RPC failed with status = UNAVAILABLE: Connection reset by peer" not preceded by any error*
- *Runtime errors "Missing infer_status notification" followed by "inference timeout"*
- *Protobuf Error "TypeError: Descriptors cannot not be created directly."*
- *TDRV error "Timestamp program stop timeout"*
- *Compiler error "module 'numpy' has no attribute 'asscalar'"*
- *Import errors 'generic_type: type "IrValue" is already registered!' or 'generic_type: type "XlaBuilder" is already registered!'*
- *Import error "import _XLAC ImportError: <>/site-packages/_XLAC.cpython-38-x86_64-linux-gnu.so: undefined symbol"*

This document shows common issues users may encounter while using PyTorch-Neuron and provides guidance how to resolve or work-around them.

8.15.1 General Troubleshooting

For XLA-related troubleshooting notes see *How to debug models in PyTorch Neuron* and PyTorch-XLA troubleshooting guide.

If your multi-worker training run is interrupted, you may need to kill all the python processes (WARNING: this kills all python processes and reload the driver):

```
killall -9 python
killall -9 python3
sudo rmmod neuron; sudo modprobe neuron
```

To turn on RT debug:

```
os.environ["NEURON_RT_LOG_LEVEL"] = "INFO"
```

To turn on Neuron NCCL debug:

```
os.environ["NCCL_DEBUG"] = "WARN"
os.environ["NCCL_DEBUG_SUBSYS"] = "ALL"
```

8.15.2 Possible Error Conditions

Non-Fatal Error OpKernel ('op: "TPU*" device_type: "CPU"')

During execution using PyTorch Neuron, you may see these non-fatal error messages:

```
E tensorflow/core/framework/op_kernel.cc:1676] OpKernel ('op: "TPURoundRobin" device_
↪type: "CPU"') for unknown op: TPURoundRobin
E tensorflow/core/framework/op_kernel.cc:1676] OpKernel ('op: "TpuHandleToProtoKey"␣
↪device_type: "CPU"') for unknown op: TpuHandleToProtoKey
```

They don't affect operation of the PyTorch Neuron and can be ignored.

XLA runtime error: "Invalid argument: Cannot assign a device for operation"

```
RuntimeError: tensorflow/compiler/xla/xla_client/xrt_computation_client.cc:490 : Check␣
↪failed: session->session()->Run(session_work->feed_inputs, session_work->outputs_
↪handles, &outputs) == ::tensorflow::Status::OK() (INVALID_ARGUMENT: Cannot assign a␣
↪device for operation XRTAllocateFromTensor: {{node XRTAllocateFromTensor}} was␣
↪explicitly assigned to /job:localservice/replica:0/task:0/device:TPU:0 but available␣
↪devices are [ /job:localservice/replica:0/task:0/device:CPU:0, /job:localservice/
↪replica:0/task:0/device:TPU_SYSTEM:0, /job:localservice/replica:0/task:0/device:XLA_
↪CPU:0 ]. Make sure the device specification refers to a valid device.
     [[XRTAllocateFromTensor]] vs. OK)
  *** Begin stack trace ***
     tensorflow::CurrentStackTrace()

     xla::util::MultiWait::Complete(std::function<void ()> const&)

     clone
  *** End stack trace ***
```

The above error indicates that the framework was not able to initialize the neuron runtime. If you get the above error, check for the following:

1. No other process is taking the neuron cores. If yes, you may have to kill that process.
2. If no process is running, try reloading the driver using `sudo rmmod neuron; sudo modprobe neuron`

Error: "Could not start gRPC server"

If you get "Could not start gRPC server" error, please check if there are any leftover python processes from a previous interrupted run and terminate them before restarting run.

```

```

Failed compilation result in the cache

All compilation results are by default saved in `Neuron Persistent Cache`. If the Neuron Compiler fails to compile a graph, we save the failed result in the cache. The reason for doing so is, if the user tries to run the same script, we want the users to error out early rather than wait for the compilation to progress and see an error at the later stage. However, there could be certain cases under which a failed compilation may be do you some environment issues. One possible reason of failure could be, during compilation the process went out of memory. This can happen if you are running multiple processes in parallel such that not enough memory is available for compilation of graph. Failure due to such reasons can be easily mitigated by re-running the compilation. In case, you want to retry a failed compilation, you can do that by passing `--retry_failed_compilation` as follows:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --retry_failed_
↪compilation'
```

This would retry the compilation and would replace a failed result in the cache with a successful compilation result.

Compilation error: "Expect ap datatype to be of type float32 float16 bfloat16 uint8"

If an XLA example fails to run because of failed compilation and one of the error messages is "Expect ap datatype to be of type float32 float16 bfloat16 uint8", then please set the environment variable `XLA_USE_32BIT_LONG=1` in your script:

```
os.environ['XLA_USE_32BIT_LONG'] = '1'
```

```

TDRV error "TDRV:tdrv_one_tmpbuf_reserve Number of ONE TMPBUF pages requested exceeded the max number of pages allowed (requested: <N>, max allowed: 16)."

If you see the TDRV error "TDRV:tdrv_one_tmpbuf_reserve Number of ONE TMPBUF pages requested exceeded the max number of pages allowed (requested: <N>, max allowed: 16)", it maybe due to model tensors requiring more device memory then available. A solution is to try training with a smaller data batch size.

```

```

Multiworker execution hangs during NCCL init

When your multi-worker execution hangs during NCCL init, you can try to reserve the port used by environment variable `NEURON_RT_ROOT_COMM_ID` by (here we use host:port localhost:48620 as an example but you can use any free port and root node's host IP):

```
sudo sysctl -w net.ipv4.ip_local_reserved_ports=48620
```

Then set the environment variable `NEURON_RT_ROOT_COMM_ID` in your script:

```
os.environ["NEURON_RT_ROOT_COMM_ID"] = "localhost:48620"
```

NRT init error "One or more engines are running. Please restart device by reloading driver"

If you see an error stating "One or more engines are running. Please restart device by reloading driver" please follow the instruction and reload the driver using "`sudo modprobe -r neuron; sudo modprobe neuron;`".

```
2021-Nov-15 20:23:27.0280 3793:3793 ERROR TDRV:tpb_eng_init_hals_v2 CRITICAL HW ERROR:
↪One or more engines are running. Please restart device by reloading driver:
sudo modprobe -r neuron; sudo modprobe neuron;
2021-Nov-15 20:23:27.0280 3793:3793 ERROR TDRV:tdrv_init_one_mla_phase2 nd0 nc0 HAL init
↪failed. error:1
```

NRT error "ERROR TDRV:kbl_model_add Attempting to load an incompatible model!"

If you see an NRT error "ERROR TDRV:kbl_model_add Attempting to load an incompatible model!" this means that the compiler neuronx-cc used to compile the model is too old. See installation instruction to update to latest compiler.

NRT error "ERROR HAL:aws_hal_sprot_config_remap_entry SPROT remap destination address must be aligned size"

If you see an NRT error "ERROR HAL:aws_hal_sprot_config_remap_entry SPROT remap destination address must be aligned size", please check the kernel version and upgrade it to the distribution's latest kernel.

For example, on Ubuntu 18.04.6 LTS, the kernel version 4.15.0-66-generic is known to cause this error when running MLP tutorial. This is due to a known bug in the kernel in aligned memory allocation. To fix this issue, please upgrade your kernel to latest version (i.e. 4.15.0-171-generic):

```
uname -a
sudo apt-get update
sudo  apt-get upgrade
sudo apt-get dist-upgrade
```

Please reboot after the upgrade. Use "uname -a" to check kernel version again after reboot.

NCCL warning : "NCCL WARN Timeout waiting for RX (waited 120 sec) - retrying"

When running multi-worker training, if a graph has collective communication operator like an `all_reduce`, it requires all the workers involved in the collective communication to load the graph in the runtime at approximately same time. If any of the worker doesn't load the graph within a 120 sec window from the first model load by any of the worker, you would see warnings like `NCCL WARN Timeout waiting for RX (waited 120 sec) - retrying`. When you see such warnings check for the following in the log messages:

1. One of the workers is compiling a graph: In multi-worker training, there is a chance that each worker builds a slightly different graph. This would result in cache miss and can result in compilation. Since the compilations during training run are serialized, the first worker can compile and load the graph with collective communication. It would then wait for 120 secs for other works to join. If they don't show up because they are compiling their own graphs, first worker would start throwing a warning message as above. The warning in this case is `non-fatal` and would go away once all workers have compiled their respective graphs and then loaded them. To identify this scenario, look for `No candidate found under ....` logs around the warning. You should also see `.....` which indicates compilation is in progress.

2. Server on one of the nodes crashed: In distributed training across multiple nodes, if the server on one node crashed, the workers on other nodes would keep waiting on model load and you would see above `timeout` logs on those nodes. To identify if the server crashed, check if you see the following error on any of the nodes:

```
`RPC failed with status = "UNAVAILABLE: Socket closed" and grpc_error_string = "{"created
↪":"@1664146011.016500243","description":"Error received from peer ipv4:10.1.24.109:
↪37379","file":"external/com_github_grpc_grpc/src/core/lib/surface/call.cc","file_line":
↪1056,"grpc_message":"Socket closed","grpc_status":14}", maybe retrying the RPC`
```

If you see the above error, then it means there is a server crash and you need to cancel the traning run.

RPC error: "RPC failed with status = 'UNAVAILABLE: Socket closed'"

When you see the above error, it means that the xrt server crashed. When you see such an error, look for the following:

1. Check for any error logs before the `RPC error`. That should indicate the root cause of server crash. Note: The actual error log might be buried because of all the `RPC error` logs that swamp the logs.
2. Sometimes the server can crash because of host OOM. This can happen when we are loading and saving checkpoints. In such cases, you only see `RPC errors` and no other log. You can check if any instance is going out of memory by using tools like dmesg

Error "Assertion `listp->slotinfo[cnt].gen <= GL(dl_tls_generation)' failed" followed by 'RPC failed with status = "UNAVAILABLE: Connection reset by peer"'

The error "Assertion `listp->slotinfo[cnt].gen <= GL(dl_tls_generation)' failed" is intermittent and occurs when using glibc 2.26. To find out the glibc version you have, you can run `ldd --version`. The workaround is to use Ubuntu 20 where glibc is 2.27.

```
INFO: Inconsistency detected by ld.so: ../elf/dl-tls.c: 488: _dl_allocate_tls_init:␣
↪Assertion `listp->slotinfo[cnt].gen <= GL(dl_tls_generation)' failed!
INFO: 2022-10-03 02:16:04.488054: W tensorflow/core/distributed_runtime/rpc/grpc_remote_
↪master.cc:157] RPC failed with status = "UNAVAILABLE: Connection reset by peer" and␣
↪grpc_error_string = "{"created":"@1664763364.487962663","description":"Error received␣
↪from peer ipv4:10.0.9.150:41677","file":"external/com_github_grpc_grpc/src/core/lib/
↪surface/call.cc","file_line":1056,"grpc_message":"Connection reset by peer","grpc_
↪status":14}", maybe retrying the RPC
```

(continues on next page)

(continued from previous page)

RPC connection error: "RPC failed with status = UNAVAILABLE: Connection reset by peer" not preceded by any error

This error may not be preceded by another error like shown in the previous section. In this case, the RPC connection error usually happens when we do distributed training across multiple nodes. When you see such error, please wait for a few minutes. It might be because some node is taking time to setup and hence the other node is not able to connect to it just yet. Once, all nodes are up, training should resume.

Runtime errors "Missing infer_status notification" followed by "inference timeout"

If you get a timeout error like below:

```
ERROR  TDRV:exec_consume_tpb_status_notifications   Missing infer_status notification:␣
↪(end:4)
ERROR  TDRV:exec_consume_infer_status_notifications (FATAL-RT-UNDEFINED-STATE) inference␣
↪timeout (600000 ms) on Neuron Device 4 NC 1, waiting for execution completion␣
↪notification
```

It maybe due to long graph execution time causing synchronization delays exceeding the default timeout. Please try increasing the timeout to larger value using `NEURON_RT_EXEC_TIMEOUT` (unit in seconds) and see if the problem is resolved.

Protobuf Error "TypeError: Descriptors cannot not be created directly."

If you install torch-neuronx after neuronx-cc, you may get the Protobuf error "TypeError: Descriptors cannot not be created directly.". To fix this, please reinstall neuronx-cc using "pip install –force-reinstall neuronx-cc".

```

    _message.Message._CheckCalledFromGeneratedFile()
TypeError: Descriptors cannot not be created directly.
If this call came from a _pb2.py file, your generated code is out of date and must be␣
↪regenerated with protoc >= 3.19.0.
If you cannot immediately regenerate your protos, some other possible workarounds are:
 1. Downgrade the protobuf package to 3.20.x or lower.
 2. Set PROTOCOL_BUFFERS_PYTHON_IMPLEMENTATION=python (but this will use pure-Python␣
↪parsing and will be much slower).
```

TDRV error "Timestamp program stop timeout"

If you see TDRV error "Timestamp program stop timeout", i.e. when rerunning a training script after it was interrupted, try first reloading the driver using `sudo modprobe -r neuron; sudo modprobe neuron;` (make sure neuron-top and/or neuron-monitor are not running).

```

Compiler error "module 'numpy' has no attribute 'asscalar'"

When you have a newer version of numpy in the Python environment, compilations may fail with the "error module 'numpy' has no attribute 'asscalar'". Please note the neuronx-cc has the following dependency on numpy "numpy<=1.20.0,>=1.13.3". To workaround this error, please do "pip install –force-reinstall neuronx-cc" to reinstall neuronx-cc with the proper dependencies.

NaNs seen with transformers version >= 4.21.0 when running HF BERT fine-tuning or pretraining with XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1

When running HuggingFace BERT (any size) fine-tuning tutorial or pretraining tutorial with transformers version >= 4.21.0 and using XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1, you will see NaNs in the loss immediately at the first step. More details on the issue can be found at pytorch/xla#4152. The workaround is to use 4.20.0 or earlier (the tutorials currently recommend version 4.15.0) or add `transformers.modeling_utils.get_parameter_dtype = lambda x: torch.bfloat16` to the Python script.

8.16 PyTorch Neuron (`torch-neuronx`) release notes

Table of Contents

- *Release [1.12.0.1.4.0]*
- *Release [1.11.0.1.2.0]*
- *Release [1.11.0.1.1.1]*

PyTorch Neuron for Trainium is a software package that enables PyTorch users to train their models on Trainium.

8.16.1 Release [1.12.0.1.4.0]

Date: 12/12/2022

Summary

What's new in this release

- Added support for PyTorch 1.12.
- Setting XLA_DOWNCAST_BF16=1 now also enables stochastic rounding by default (as done with XLA_USE_BF16=1).
- Added support for *capturing snapshots* of inputs, outputs and graph HLO for debug.
- Fixed issue with parallel compile error when both train and evaluation are enabled in HuggingFace fine-tuning tutorial.
- Added support for LAMB optimizer in FP32 mode.

Resolved Issues

NaNs seen with transformers version >= 4.21.0 when running HF BERT fine-tuning or pretraining with XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1

When running HuggingFace BERT (any size) fine-tuning tutorial or pretraining tutorial with transformers version >= 4.21.0 and using XLA_USE_BF16=1 or XLA_DOWNCAST_BF16=1, you will see NaNs in the loss immediately at the first step. More details on the issue can be found at pytorch/xla#4152. The workaround is to use 4.20.0 or earlier (the tutorials currently recommend version 4.15.0) or add the line `transformers.modeling_utils.get_parameter_dtype = lambda x: torch.bfloat16` to your Python training script (as now done in latest tutorials). A permanent fix will become part of an upcoming HuggingFace transformers release.

Known Issues and Limitations

Convolution is not supported

In this release, convolution is not supported.

Number of data parallel training workers on one Trn1 instance

The number of workers used in single-instance data parallel training can be one of the following values: 1 or 2 for trn1.2xlarge and 1, 2, 8 or 32 for trn1.32xlarge.

8.16.2 Release [1.11.0.1.2.0]

Date: 10/27/2022

Summary

What's new in this release

- Added support for argmax.
- Clarified error messages for runtime errors `NRT_UNINITIALIZED` and `NRT_CLOSED`.
- When multi-worker training is launched using torchrun on one instance, framework now handles runtime state cleanup at end of training.

Resolved Issues

Drop-out rate ignored in dropout operation

A known issue in the compiler's implementation of dropout caused drop-rate to be ignored in the last release. It is fixed in the current release.

Runtime error "invalid offset in Coalesced_memloc_…" followed by "Failed to process dma block: 1703"

Previously, when running MRPC fine-tuning tutorial with `bert-base-*` model, you would encounter runtime error "invalid offset in Coalesced_memloc_…" followed by "Failed to process dma block: 1703". This is fixed in the current release.

Compilation error: "TongaSBTensor[0x7fb2a46e0830]:TongaSB partitions[0] uint8 %138392[128, 512]"

Previously, when compiling MRPC fine-tuning tutorial with `bert-large-*` and FP32 (no XLA_USE_BF16=1) for two workers or more, you would encounter compiler error that looks like `Error message: TongaSBTensor[0x7fb2a46e0830]:TongaSB partitions[0] uint8 %138392[128, 512]` followed by `Error class: KeyError`. Single worker fine-tuning is not affected. This is fixed in the current release.

Known Issues and Limitations

Convolution is not supported

In this release, convolution is not supported.

Number of data parallel training workers on one Trn1 instance

The number of workers used in single-instance data parallel training can be one of the following values: 1 or 2 for trn1.2xlarge and 1, 2, 8 or 32 for trn1.32xlarge.

8.16.3 Release [1.11.0.1.1.1]

Date: 10/10/2022

Summary

This is the initial release of PyTorch Neuron that supports Trainium for users to train their models on the new EC2 Trn1 instances.

What's new in this release

Announcing the first PyTorch Neuron release for training.

- XLA device support for Trainium
- PyTorch 1.11 with XLA backend support in torch.distributed
- torch-xla distributed support
- Single-instance and multi-instance distributed training using torchrun
- Support for ParallelCluster and SLURM with node-level scheduling granularity
- Persistent cache for compiled graph
- *neuron_parallel_compile* utility to help speed up compilation

- Optimizer support: SGD, AdamW
- Loss functions supported: NLLLoss
- Python versions supported: 3.7, 3.8
- Multi-instance training support with EFA
- Support PyTorch's BF16 automatic mixed precision

Known Issues and Limitations

Convolution is not supported

In this release, convolution is not supported.

Number of data parallel training workers on one Trn1 instance

The number of workers used in single-instance data parallel training can be one of the following values: 1 or 2 for trn1.2xlarge and 1, 2, 8 or 32 for trn1.32xlarge.

Drop-out rate ignored in dropout operation

A known issue in the compiler's implementation of dropout caused drop-rate to be ignored. Will be fixed in a follow-on release.

Runtime error "invalid offset in Coalesced_memloc_…" followed by "Failed to process dma block: 1703"

Currently, when running MRPC fine-tuning tutorial with `bert-base-*` model, you will encounter runtime error "invalid offset in Coalesced_memloc_…" followed by "Failed to process dma block: 1703". This issue will be fixed in an upcoming release.

Compilation error: "TongaSBTensor[0x7fb2a46e0830]:TongaSB partitions[0] uint8 %138392[128, 512]"

When compiling MRPC fine-tuning tutorial with `bert-large-*` and FP32 (no XLA_USE_BF16=1) for two workers or more, you will encounter compiler error that looks like `Error message: TongaSBTensor[0x7fb2a46e0830]: TongaSB partitions[0] uint8 %138392[128, 512]` followed by `Error class: KeyError`. Single worker fine-tuning is not affected. This issue will be fixed in an upcoming release.

This document is relevant for: `Trn1`

Inference

Setup Guide for Inf1

This document is relevant for: `Inf1`

8.17 Install PyTorch Neuron (`torch-neuron`)

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

8.17.1 Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.12.1

8.17.2 Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.12.1

Ubuntu 18 AMI/Ubuntu 20 AMI

```

8.17.3 Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.12.1

Ubuntu 18 AMI/Ubuntu 20 AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Configure Linux for Neuron repository updates

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

8.18 Update to latest PyTorch Neuron (`torch-neuron`)

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

8.18.1 Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.12.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

8.18.2 Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.12.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

8.18.3 Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.12.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Update OS packages
sudo apt-get update -y

8.19 Install previous PyTorch Neuron releases (`torch-neuron`)

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

This document is relevant for: `Inf1`

8.19.1 Install PyTorch Neuron (Neuron 2.5.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.12.1

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

↪0 torchvision
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.12.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Configure Linux for Neuron repository updates

This document is relevant for: `Inf1`

8.19.2 Install PyTorch Neuron (Neuron 2.4.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.11.0

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

↪0 torchvision
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.11.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

8.19.3 Install PyTorch Neuron (Neuron 2.3.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.11.0

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.11.0

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.11.0

This document is relevant for: `Inf1`

8.19.4 Install PyTorch Neuron (Neuron 1.19.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.11.0

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.11.0

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.11.0

This document is relevant for: `Inf1`

8.19.5 Install PyTorch Neuron (Neuron 1.18.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.10.1

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.10.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
#######################################################
#   Only for Ubuntu 20 - Install Python3.7
#
# sudo add-apt-repository ppa:deadsnakes/ppa
# sudo apt-get install python3.7
#
#######################################################
# Install Python venv and activate Python virtual environment to install
# Neuron pip packages.
sudo apt-get install -y python3.7-venv g++
python3.7 -m venv pytorch_venv
source pytorch_venv/bin/activate
pip install -U pip

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron PyTorch
pip install torch-neuron==1.10.1.2.2.0.0 neuron-cc[tensorflow] "protobuf==3.20.1"==1.10.
↪3.0 torchvision
```

Amazon Linux AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Install Python venv and activate Python virtual environment to install
# Neuron pip packages.
sudo yum install -y python3.7-venv gcc-c++
python3.7 -m venv pytorch_venv
source pytorch_venv/bin/activate
pip install -U pip

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron PyTorch
pip install torch-neuron==1.10.1.2.2.0.0 neuron-cc[tensorflow] "protobuf==3.20.1"==1.10.
↪3.0 torchvision
```

Ubuntu DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Note: There is no DLAMI Conda environment for this framework version
#       Framework will be installed/updated inside a Python environment

# Activate PyTorch

↪0 torchvision
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

8.19.6 Install PyTorch Neuron (Neuron 1.17.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.10.1

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.10.1

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

8.19.7 Install PyTorch Neuron (Neuron 1.16.3)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.9.1

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.9.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
#######################################################
#   Only for Ubuntu 20 - Install Python3.6
#
# sudo add-apt-repository ppa:deadsnakes/ppa
# sudo apt-get install python3.6
#
#######################################################
# Install Python venv and activate Python virtual environment to install
# Neuron pip packages.
sudo apt-get install -y python3.6-venv g++
python3.6 -m venv pytorch_venv
source pytorch_venv/bin/activate
pip install -U pip

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron PyTorch

↪5.0 torchvision
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

This document is relevant for: `Inf1`

8.19.8 Install PyTorch Neuron (Neuron 1.16.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.9.1

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.9.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

8.19.9 Install PyTorch Neuron (Neuron 1.16.1)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.9.1

↪3.0 torchvision
```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.9.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

↪3.0 torchvision
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.9.1

8.19.10 Install PyTorch Neuron (Neuron 1.15.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

8.19.11 Install PyTorch Neuron (Neuron 1.15.1)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

PyTorch 1.8.1

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.8.1

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

8.19.12 Install PyTorch Neuron (Neuron 1.15.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

8.19.13 Install PyTorch Neuron (Neuron 1.14.2)

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

PyTorch 1.8.1

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

8.20 Install with support for cxx11 ABI

Warning: The intended user of this guide is using a custom built version of `torch` or compiling a non-python application which must be built using the cxx11 ABI.

Most applications do not require this specialized distribution.

For regular installation instructions see: *Fresh install*

The standard `torch-neuron` packages (which are normally installed according to the *Fresh install* guide) are compiled with the pre-cxx11 ABI and linked against the pre-cxx11 `libtorch`. These compilation options ensure that the `torch-neuron` ABI matches the *publicly* released version of the `torch` package that is installed from the default PyPI index.

To support applications with specific ABI requirements, Neuron distributes packages which are linked against the cxx11 version of `libtorch`. These `torch-neuron` packages are built using the `-D_GLIBCXX_USE_CXX11_ABI=1` compilation flag.

The only difference between these packages and the standard packages is the torch plugin library contained within the package. This is the `libtorchneuron.so` library located in the `torch_neuron/lib/` package directory. All other libraries and python files within the packages are identical. This means that these cxx11-compatible packages are drop-in replacements in environments that are incompatible with the standard releases of `torch-neuron`. Behavior is identical whether compiling models or executing inferences.

8.20.1 Installation

All versions of the library are available to download from the following pip index:

```
https://pip.repos.neuron.amazonaws.com/cxx11
```

To install a wheel, it is recommended to use the `--no-deps` flag since versions of `torch` compiled using the cxx11 ABI are not distributed on this index.

```
pip install --extra-index-url=https://pip.repos.neuron.amazonaws.com/cxx11 torch-neuron -
↪-no-deps
```

Specific versions of `torch-neuron` with cxx11 ABI support can be installed just like standard versions of `torch-neuron`.

```
pip install --extra-index-url=https://pip.repos.neuron.amazonaws.com/cxx11 "torch-neuron>
↪=1.8" --no-deps
pip install --extra-index-url=https://pip.repos.neuron.amazonaws.com/cxx11 "torch-
↪neuron==1.9.1" --no-deps
pip install --extra-index-url=https://pip.repos.neuron.amazonaws.com/cxx11 "torch-neuron
↪<1.10" --no-deps
```

Important: This pip index does not include a distribution of `torch` compiled with the new cxx11 ABI. The intent of this index is *only* to provide Neuron SDK wheels.

The version of `torch` that is distributed on the default PyPI index is compiled with the old pre-cxx11 ABI.

If a cxx11 `torch-neuron` package is installed *with* dependencies using the *default* PyPI index, then the installed version of `torch` will be using the pre-cxx11 ABI and `torch-neuron` will be using the cxx11 ABI. This ABI mismatch will lead to errors in both python usage and at link time for non-python applications.

8.20.2 FAQ

When should I use a cxx11 torch-neuron wheel?

Distributions compiled with the new cxx11 ABI should only be used in the following cases:

1. You have built your own version of `torch` which uses the new cxx11 ABI and need a corresponding version of `torch-neuron` that is compatible.
2. You are compiling an application against a `libtorch` which uses the cxx11 ABI and would like to include `libtorchneuron.so` as well. Torch distributes these cxx11 `libtorch` libraries with a `libtorch-cxx11` prefix.

   Example:

   ```
   https://download.pytorch.org/libtorch/cpu/libtorch-cxx11-abi-shared-with-
   ↪deps-1.10.2%2Bcpu.zip
   ```

Can I download a library/header zip file similar to the torch distribution?

Currently `torch-neuron` does not distribute a bundled library `.zip` with only library/header files.

The recommended alternative when compiling `libtorchneuron.so` into a non-python application is to install the `torch-neuron` wheel using `pip` according to the installation instructions. Then use the `libtorchneuron.so` library from within the python `site-packages` directory.

A second alternative to isolate the package contents from a python environment is to download the wheel and unpack the contents:

```
pip download --extra-index-url=https://pip.repos.neuron.amazonaws.com/cxx11 torch-neuron␣
↪--no-deps
wheel unpack torch_neuron-*.whl
```

If the exact version of the `torch-neuron` package is known and no python/pip is available in the build environment, an alternative to is fetch the package file directly and `unzip` the wheel:

```
wget https://pip.repos.neuron.amazonaws.com/cxx11/torch-neuron/torch_neuron-<VERSION>-
↪py3-none-any.whl
unzip torch_neuron-<VERSION>-py3-none-any.whl
```

How can I know which ABI torch-neuron is using?

Packages which use the pre-cxx11 ABI have no local identifier and use the following version scheme:

```
<torch version>.<neuron version>
```

Packages which use the cxx11 ABI have a `+cxx11` local identifier and use following version scheme:

```
<torch version>.<neuron version>+cxx11
```

This allows the ABI to be validated in the by inspecting the local identifier (or version suffix).

Example:

```
1.8.1.0.0.0.0+cxx11
1.9.1.0.0.0.0+cxx11
1.10.2.0.0.0.0+cxx11
```

How can I know which ABI torch is using?

The `torch` python package provides an API at the that allows you to check if the underlying `libtorch` was compiled with the cxx11 ABI:

```
import torch
torch.compiled_with_cxx11_abi()  # True/False
```

Currently `torch-neuron` does not have an equivalent API. If the cxx11 ABI was used, it will be visible in the version string (See *How can I know which ABI torch-neuron is using?*).

8.20.3 Troubleshooting

What python errors could I see if I mix ABI versions?

Using a version of `torch` compiled with the cxx11 ABI will trigger an error in the python interpreter when importing a version of `torch-neuron` using the old (pre-cxx11) ABI from the standard index. This will manifest as an error when the `import torch_neuron` statement is executed.

```
Traceback (most recent call last):
  File "/python3.7/site-packages/torch_neuron/__init__.py", line 64, in <module>
    _register_extension()

↪ZN5torch3jit17parseSchemaOrNameERKNSt7__cxx1112basic_stringIcSt11char_traitsIcESaIcEEE
```

In either of these cases, the remedy is to ensure that the ABI of the `torch` distribution matches the ABI of the `torch-neuron` distribution.

What compiler/linking errors could I see if I mix ABI versions?

If you link an application which uses the old (pre-cxx11) ABI `libtorchneuron.so` with a cxx11 version of `torch`, this will trigger a link error.

```
libtorchneuron.so: undefined reference to `torch::detail::class_base::class_base(std::
↪string const&, std::string const&, std::string, std::type_info const&, std::type_info␣
↪const&)'
libtorchneuron.so: undefined reference to `c10::Error::Error(c10::SourceLocation, std::
↪string)'
libtorchneuron.so: undefined reference to `c10::detail::torchInternalAssertFail(char␣
↪const*, char const*, unsigned int, char const*, std::string const&)'
libtorchneuron.so: undefined reference to `c10::ClassType::getMethod(std::string const&)␣
↪const'
libtorchneuron.so: undefined reference to `c10::ivalue::ConstantString::create(std::
↪string)'
libtorchneuron.so: undefined reference to `c10::DeviceTypeName(c10::DeviceType, bool)'
libtorchneuron.so: undefined reference to `torch::jit::parseSchema(std::string const&)'
libtorchneuron.so: undefined reference to `unsigned short caffe2::TypeMeta::_typeMetaData
↪<std::string>()'
libtorchneuron.so: undefined reference to `c10::Warning::warn(c10::SourceLocation const&,
↪ std::string const&, bool)'
libtorchneuron.so: undefined reference to `torch::jit::parseSchemaOrName(std::string␣
↪const&)'
libtorchneuron.so: undefined reference to `c10::Symbol::fromQualString(std::string const&
↪)'
libtorchneuron.so: undefined reference to `c10::Error::Error(std::string, std::string,␣
↪void const*)'
libtorchneuron.so: undefined reference to `c10::detail::infer_schema::make_function_
↪schema(std::string&&, std::string&&, c10::ArrayRef<c10::detail::infer_schema::
↪ArgumentDef>, c10::ArrayRef<c10::detail::infer_schema::ArgumentDef>)'
```

(continues on next page)

(continued from previous page)

```
libtorchneuron.so: undefined reference to `c10::detail::torchCheckFail(char const*, char␣
↪const*, unsigned int, std::string const&)'
libtorchneuron.so: undefined reference to `torch::jit::canonicalSchemaString(c10::
↪FunctionSchema const&)'
```

Similarly, an error will also occur in the opposite scenario where the cxx11 `libtorchneuron.so` library is used with the pre-cxx11 `libtorch`:

```
libtorchneuron.so: undefined reference to `c10::ivalue::ConstantString::create(std::__
↪cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> >)'
libtorchneuron.so: undefined reference to `torch::jit::parseSchemaOrName(std::__cxx11::
↪basic_string<char, std::char_traits<char>, std::allocator<char> > const&)'
libtorchneuron.so: undefined reference to `c10::Error::Error(c10::SourceLocation, std::__
↪cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> >)'
libtorchneuron.so: undefined reference to `c10::Error::Error(std::__cxx11::basic_string
↪<char, std::char_traits<char>, std::allocator<char> >, std::__cxx11::basic_string<char,
↪ std::char_traits<char>, std::allocator<char> >, void const*)'
libtorchneuron.so: undefined reference to `torch::jit::canonicalSchemaString[abi:
↪cxx11](c10::FunctionSchema const&)'
libtorchneuron.so: undefined reference to `torch::detail::class_base::class_base(std::__
↪cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> > const&, std::_
↪_cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> > const&, std::
↪__cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> >, std::type_
↪info const&, std::type_info const&)'
libtorchneuron.so: undefined reference to `c10::detail::torchInternalAssertFail(char␣
↪const*, char const*, unsigned int, char const*, std::__cxx11::basic_string<char, std::
↪char_traits<char>, std::allocator<char> > const&)'
libtorchneuron.so: undefined reference to `c10::detail::torchCheckFail(char const*, char␣
↪const*, unsigned int, std::__cxx11::basic_string<char, std::char_traits<char>, std::
↪allocator<char> > const&)'
libtorchneuron.so: undefined reference to `c10::detail::infer_schema::make_function_
↪schema(std::__cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> >&
↪&, std::__cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> >&&,␣
↪c10::ArrayRef<c10::detail::infer_schema::ArgumentDef>, c10::ArrayRef<c10::detail::
↪infer_schema::ArgumentDef>)'
libtorchneuron.so: undefined reference to `torch::jit::parseSchema(std::__cxx11::basic_
↪string<char, std::char_traits<char>, std::allocator<char> > const&)'
libtorchneuron.so: undefined reference to `c10::DeviceTypeName[abi:cxx11](c10::
↪DeviceType, bool)'
libtorchneuron.so: undefined reference to `c10::Symbol::fromQualString(std::__cxx11::
↪basic_string<char, std::char_traits<char>, std::allocator<char> > const&)'
libtorchneuron.so: undefined reference to `unsigned short caffe2::TypeMeta::_typeMetaData
↪<std::__cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> > >()'
libtorchneuron.so: undefined reference to `c10::ClassType::getMethod(std::__cxx11::basic_
↪string<char, std::char_traits<char>, std::allocator<char> > const&) const'
libtorchneuron.so: undefined reference to `c10::Warning::warn(c10::SourceLocation const&,
↪ std::__cxx11::basic_string<char, std::char_traits<char>, std::allocator<char> > const&
↪, bool)'
```

In either of these cases, the remedy is to ensure that the ABI of the `libtorch` distribution matches the ABI of the `libtorchneuron.so` distribution.

The `torch` ABI must match the `torch-neuron` ABI or an error will occur.

8.21 ResNet50 model for Inferentia

8.21.1 Introduction:

In this tutorial we will compile and deploy a ResNet50 model for inference on Inferentia.

This Jupyter notebook should run on an inf1.6xlarge instance. The inference part of this tutorial requires an inf1 instance, not the compilation stage. For simplicity we will run this tutorial on an inf1.6xlarge, but in real life scenarios the compilation should be done on a compute instance and the deployment on an inf1 instance to save costs.

In this tutorial we provide three main sections:

1. Compile the ResNet50 model and infer with a batch size of 1
2. Run the same compiled model on multiple NeuronCores using `torch.neuron.DataParallel` and dynamic batching
3. Compile the ResNet50 model with a batch size of 5 and run it on multiple NeuronCores using `torch.neuron.DataParallel` for optimal performance on Inferentia

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the PyTorch Installation Guide. You can select the kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

8.21.2 Install Dependencies:

This tutorial requires the following pip packages:

- `torch>=1.8`
- `torch-neuron`
- `torchvision`
- `neuron-cc[tensorflow]`

These will be installed by default when configuring your environment using the Neuron PyTorch setup guide.

8.21.3 Compile model for Neuron

The following step will compile the ResNet50 model for Inferentia. This will take a few minutes. At the end of script execution, the compiled model is saved as `resnet50_neuron.pt` in your local directory

[ ]:
```
import torch
from torchvision import models, transforms, datasets
import torch_neuron

# Create an example input for compilation
image = torch.zeros([1, 3, 224, 224], dtype=torch.float32)

# Load a pretrained ResNet50 model
model = models.resnet50(pretrained=True)

# Tell the model we are using it for evaluation (not training)
model.eval()

# Analyze the model - this will show operator support and operator count
torch.neuron.analyze_model(model, example_inputs=[image])

# Compile the model using torch.neuron.trace to create a Neuron model
# that that is optimized for the Inferentia hardware
model_neuron = torch.neuron.trace(model, example_inputs=[image])

# The output of the compilation step will report the percentage of operators that
# are compiled to Neuron, for example:
#
# INFO:Neuron:The neuron partitioner created 1 sub-graphs
# INFO:Neuron:Neuron successfully compiled 1 sub-graphs, Total fused subgraphs = 1,␣
↪Percent of model sub-graphs successfully compiled = 100.0%
#
# We will also be warned if there are operators that are not placed on the Inferentia␣
↪hardware

# Save the compiled model
model_neuron.save("resnet50_neuron.pt")
```

8.21.4 Run inference on Inferentia

We can use the compiled Neuron model to run inference on Inferenita.

In the following example, we preprocess a sample image for inference using the CPU model and Neuron model. We compare the predicted labels from the CPU model and Neuron model to verify that they are the same.

Important: Do not perform inference with a Neuron traced model on a non-Neuron supported instance, as the results will not be calculated properly.

Define a preprocessing function

We define a basic image preprocessing function that loads a sample image and labels, normalizes and batches the image, and transforms the image into a tensor for inference using the compiled Neuron model.

[ ]:
```
import json
import os
from urllib import request

# Create an image directory containing a sample image of a small kitten
os.makedirs("./torch_neuron_test/images", exist_ok=True)
request.urlretrieve("https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/
↪docs/images/kitten_small.jpg",
                    "./torch_neuron_test/images/kitten_small.jpg")

# Fetch labels to output the top classifications
request.urlretrieve("https://s3.amazonaws.com/deep-learning-models/image-models/imagenet_
↪class_index.json","imagenet_class_index.json")
idx2label = []

# Read the labels and create a list to hold them for classification
with open("imagenet_class_index.json", "r") as read_file:
    class_idx = json.load(read_file)
    idx2label = [class_idx[str(k)][1] for k in range(len(class_idx))]
```

[ ]:
```
import numpy as np

def preprocess(batch_size=1, num_neuron_cores=1):
    # Define a normalization function using the ImageNet mean and standard deviation
    normalize = transforms.Normalize(
        mean=[0.485, 0.456, 0.406],
        std=[0.229, 0.224, 0.225])

    # Resize the sample image to [1, 3, 224, 224], normalize it, and turn it into a␣
↪tensor
    eval_dataset = datasets.ImageFolder(
        os.path.dirname("./torch_neuron_test/"),
        transforms.Compose([
        transforms.Resize([224, 224]),
        transforms.ToTensor(),
        normalize,
        ])
    )
    image, _ = eval_dataset[0]
    image = torch.tensor(image.numpy()[np.newaxis, ...])

    # Create a "batched" image with enough images to go on each of the available␣
↪NeuronCores
    # batch_size is the per-core batch size
    # num_neuron_cores is the number of NeuronCores being used
    batch_image = image
    for i in range(batch_size * num_neuron_cores - 1):
        batch_image = torch.cat([batch_image, image], 0)
```

(continues on next page)

(continued from previous page)

```
    return batch_image
```

Run inference using the Neuron model

We import the necessary python modules, load the torch-neuron compiled model, and run inference on Inferentia.

By default, the Neuron model will run on a single NeuronCore. In the next section, we will see how to run the Neuron model on multiple NeuronCores to fully saturate our hardware for optimal performance on Inferentia.

[ ]:
```
import torch
from torchvision import models, transforms, datasets
import torch_neuron

# Get a sample image
image = preprocess()

# Run inference using the CPU model
output_cpu = model(image)

# Load the compiled Neuron model
model_neuron = torch.jit.load('resnet50_neuron.pt')

# Run inference using the Neuron model
output_neuron = model_neuron(image)

# Verify that the CPU and Neuron predictions are the same by comparing
# the top-5 results
top5_cpu = output_cpu[0].sort()[1][-5:]
top5_neuron = output_neuron[0].sort()[1][-5:]

# Lookup and print the top-5 labels
top5_labels_cpu = [idx2label[idx] for idx in top5_cpu]
top5_labels_neuron = [idx2label[idx] for idx in top5_neuron]
print("CPU top-5 labels: {}".format(top5_labels_cpu))
print("Neuron top-5 labels: {}".format(top5_labels_neuron))
```

8.21.5 Run Inference using torch.neuron.DataParallel

To fully leverage the Inferentia hardware we want to use all avaialable NeuronCores. An inf1.xlarge and inf1.2xlarge have four NeuronCores, an inf1.6xlarge has 16 NeuronCores, and an inf1.24xlarge has 64 NeuronCores. For maximum performance on Inferentia hardware, we can use `torch.neuron.DataParallel` to utilize all available NeuronCores.

`torch.neuron.DataParallel` implements data parallelism at the module level by duplicating the Neuron model on all available NeuronCores and distributing data across the different cores for parallelized inference.

In the following section, we will run inference using the `torch.neuron.DataParallel` module to fully saturate the Inferentia hardware. We benchmark the model to collect throughput and latency statistics.

Note: `torch.neuron.DataParallel` is new with Neuron 1.16.0. Please ensure you are using the latest Neuron package to run the following sections.

Define a benchmarking function

We create a function that handles benchmarking the Neuron model to collect throughput and latency metrics.

[ ]:
```
from time import time

def benchmark(model, image):
    print('Input image shape is {}'.format(list(image.shape)))

    # The first inference loads the model so exclude it from timing
    results = model(image)

    # Collect throughput and latency metrics
    latency = []
    throughput = []

    # Run inference for 100 iterations and calculate metrics
    num_infers = 100
    for _ in range(num_infers):
        delta_start = time()
        results = model(image)
        delta = time() - delta_start
        latency.append(delta)
        throughput.append(image.size(0)/delta)

    # Calculate and print the model throughput and latency
    print("Avg. Throughput: {:.0f}, Max Throughput: {:.0f}".format(np.mean(throughput),␣
↪np.max(throughput)))
    print("Latency P50: {:.0f}".format(np.percentile(latency, 50)*1000.0))
    print("Latency P90: {:.0f}".format(np.percentile(latency, 90)*1000.0))
    print("Latency P95: {:.0f}".format(np.percentile(latency, 95)*1000.0))
    print("Latency P99: {:.0f}\n".format(np.percentile(latency, 99)*1000.0))
```

Run Inference using torch.neuron.DataParallel

We create the `torch.neuron.DataParallel` module using the compiled Neuron model, get a sample image, and benchmark the parallelized model on Neuron.

[ ]:
```
# Create a torch.neuron.DataParallel module using the compiled Neuron model
# By default, torch.neuron.DataParallel will use four cores on an inf1.xlarge
# or inf1.2xlarge, 16 cores on an inf1.6xlarge, and 24 cores on an inf1.24xlarge
model_neuron_parallel = torch.neuron.DataParallel(model_neuron)

# Get sample image with batch size=1 per NeuronCore
batch_size = 1

# For an inf1.xlarge or inf1.2xlarge, set num_neuron_cores = 4
num_neuron_cores = 16

image = preprocess(batch_size=batch_size, num_neuron_cores=num_neuron_cores)

# Benchmark the model
benchmark(model_neuron_parallel, image)
```

8.21.6 Run inference with dynamic batch sizes

Batch size has a direct impact on model performance. The Inferentia chip is optimized to run with small batch sizes. This means that a Neuron compiled model can outperform a GPU model, even if running single digit batch sizes.

As a general best practice, we recommend optimizing your model's throughput by compiling the model with a small batch size and gradually increasing it to find the peak throughput on Inferentia.

Dynamic batching is a feature that allows you to use tensor batch sizes that the Neuron model was not originally compiled against. This is necessary because the underlying Inferentia hardware will always execute inferences with the batch size used during compilation. Fixed batch size execution allows tuning the input batch size for optimal performance. For example, batch size 1 may be best suited for an ultra-low latency on-demand inference application, while batch size > 1 can be used to maximize throughput for offline inferencing. Dynamic batching is implemented by slicing large input tensors into chunks that match the batch size used during the `torch.neuron.trace` compilation call.

The `torch.neuron.DataParallel` class automatically enables dynamic batching on eligible models. This allows us to run inference in applications that have inputs with a variable batch size without needing to recompile the model.

In the following example, we use the same `torch.neuron.DataParallel` module to run inference using several different batch sizes. Notice that latency increases consistently as the batch size increases. Throughput increases as well, up until a certain point where the input size becomes too large to be efficient.

[ ]:
```
# using the same DataParallel model_neuron_parallel model, we can run
# inference on inputs with a variable batch size without recompiling
batch_sizes = [2, 3, 4, 5, 6, 7]
for batch_size in batch_sizes:
    print('Batch size: {}'.format(batch_size))
    image = preprocess(batch_size=batch_size, num_neuron_cores=num_neuron_cores)

    # Benchmark the model for each input batch size
    benchmark(model_neuron_parallel, image)
```

8.21.7 Compile and Infer with different batch sizes on multiple NeuronCores

Dynamic batching using small batch sizes can result in sub-optimal throughput because it involves slicing tensors into chunks and iteratively sending data to the hardware. Using a larger batch size at compilation time can use the Inferentia hardware more efficiently in order to maximize throughput. You can test the tradeoff between individual request latency and total throughput by fine-tuning the input batch size.

In the following example, we recompile our model using a batch size of 5 and run the model using `torch.neuron.DataParallel` to fully saturate our Inferentia hardware for optimal performance.

[ ]:
```
# Create an input with batch size 5 for compilation
batch_size = 5
image = torch.zeros([batch_size, 3, 224, 224], dtype=torch.float32)

# Recompile the ResNet50 model for inference with batch size 5
model_neuron = torch.neuron.trace(model, example_inputs=[image])

# Export to saved model
model_neuron.save("resnet50_neuron_b{}.pt".format(batch_size))
```

Run inference with batch size of 5 using the Neuron model compiled for a batch size of 5.

[ ]:
```
batch_size = 5

# Load compiled Neuron model
model_neuron = torch.jit.load("resnet50_neuron_b{}.pt".format(batch_size))

# Create DataParallel model
model_neuron_parallel = torch.neuron.DataParallel(model_neuron)

# Get sample image with batch size=5
image = preprocess(batch_size=batch_size, num_neuron_cores=num_neuron_cores)

# Benchmark the model
benchmark(model_neuron_parallel, image)
```

You can experiment with different batch size values to see what gives the best overall throughput on Inferentia.

8.22 Evaluate YOLO v4 on Inferentia

8.22.1 Introduction

This tutorial walks through compiling and evaluating YOLO v4 model implemented in PyTorch on Inferentia.

The tutorial has five main sections:

1. Define YOLO v4 model in PyTorch
2. Download the COCO 2017 evaluation dataset and define the data loader function
3. Build, Compile, and Save Neuron-Optimized YOLO v4 TorchScript
4. Evaluate Accuracy on the COCO 2017 Dataset
5. Benchmark COCO Dataset Performance of the Neuron-Optimized TorchScript

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the PyTorch Installation Guide. You can select the kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

8.22.2 Install Dependencies:

This tutorial requires the following pip packages:

- `torch-neuron`
- `torchvision`
- `pillow`
- `pycocotools`
- `neuron-cc[tensorflow]`

Many of these packages will be installed by default when configuring your environment using the Neuron PyTorch setup guide. The additional dependencies must be installed here.

[ ]:
```
!pip install --upgrade pillow pycocotools
```

8.22.3 Part 1: Define YOLO v4 model in PyTorch

The following PyTorch model definition is from https://github.com/Tianxiaomo/pytorch-YOLOv4/.

[ ]:
```
import numpy as np
import torch
import torch.neuron
from torch import nn
import torch.nn.functional as F
import os
import warnings

# Setting up NeuronCore groups for inf1.6xlarge with 16 cores
n_cores = 16 # This value should be 4 on inf1.xlarge and inf1.2xlarge
os.environ['NEURON_RT_NUM_CORES'] = str(n_cores)

class Mish(torch.nn.Module):
    def __init__(self):
        super().__init__()

    def forward(self, x):
        x = x * (torch.tanh(torch.nn.functional.softplus(x)))
        return x

class Upsample(nn.Module):
    def __init__(self):
        super(Upsample, self).__init__()

    def forward(self, x, target_size, inference=False):

download_file_from_google_drive('1wv_LiFeCRYwtpkqREPeI13-gPELBDwuJ', './yolo_v4.pth')
```

8.22.5 Part 3: Build, Compile, and Save Neuron-Optimized YOLO v4 TorchScript

Construct model and load pretrained checkpoint

[ ]:
```
model = Yolov4(yolov4conv137weight=None, n_classes=80, inference=True)
weightfile = "./yolo_v4.pth"
pretrained_dict = torch.load(weightfile, map_location=torch.device('cpu'))
model.load_state_dict(pretrained_dict)
model.eval()
```

Execute inference for a single image and display output

[ ]:
```
import matplotlib.pyplot as plt
import matplotlib.patches as patches

image_orig, _ = next(iter(orig_coco_val_data_loader))
image, _ = next(iter(coco_val_data_loader))
boxes, scores = model(image)
boxes, scores, labels = postprocess(boxes, scores)
result_dict = get_results_as_dict(boxes, scores, labels, image_orig)

fig, ax = plt.subplots(figsize=(10, 10))
ax.imshow(image_orig.numpy().squeeze(0).transpose(1, 2, 0))
for xywh, _ in zip(result_dict['boxes'], result_dict['labels']):
    x, y, w, h = xywh
    rect = patches.Rectangle((x, y), w, h, linewidth=1, edgecolor='g', facecolor='none')
    ax.add_patch(rect)
plt.show()
```

Run compilation with manually specified device placement

First, inspect the model without running compilation by adding the `skip_compiler=True` argument to the `torch.neuron.trace` call.

```
[ ]: model_neuron_for_inspection = torch.neuron.trace(model, image, skip_compiler=True)
print(model_neuron_for_inspection)
```

Inspecting the model, we discover that there are many `aten::slice` operations in some submodules called `YoloLayer`. Although these operations are supported by the neuron-cc compiler, they are not going to run efficiently on the Inferentia hardware. To work it around, we recommend to manually place these operators on CPU.

To manually place `YoloLayer` on CPU, we may make use of the `subgraph_builder_function` argument in `torch.neuron.trace`. It is a callback function that returns `True` or `False` based on information available in `node`. The typical use is a condition based on either `node.name` or `node.type_string`.

```
[ ]: def subgraph_builder_function(node):
    return 'YoloLayer' not in node.name

model_neuron = torch.neuron.trace(model, image, subgraph_builder_function=subgraph_
↪builder_function)
model_neuron.save('yolo_v4_neuron.pt')
```

Compilation is now finished and the compiled model has been saved to a local file called 'yolo_v4_neuron.pt'. Saving is important due to the slow compilation process.

8.22.6 Part 4: Evaluate Accuracy on the COCO 2017 Dataset

Load compiled model and run inference

To validate accuracy of the compiled model, lets run inference on the COCO 2017 validation dataset. We start by defining a helper function `run_inference`.

```
[ ]: def run_inference(dataloader, dataloader_orig, model, convert=True, modelName=''):
    """
    Run Yolo V4 inference on the COCO dataset.

    Args:
        dataloader (iterable): Data loader of input processed images and labels.
        dataloader_orig (iterable): Data loader with original images.
        model (torch.nn.Module): The torch model to run inference against.
        convert (bool): Set to False when using a vanilla torchvision model that
            does not need to be transformed into coco format.

    Returns:
        imgIds (list): The list of images with predictions.
        cocoDt (pycocotools.coco.COCO): Contains the predictions from the model
            in coco format.
    """
    print('\n================ Starting Inference on {} Images using {} model␣
↪================\n'.format(
        len(dataloader), modelName))
```

(continues on next page)

(continued from previous page)

               output in zip(targets, [outputs])}

        # add the image id to imgIds
        image_id = targets[0]["image_id"].item()
        imgIds.append(image_id)

        # convert the predicition into cocoDt results
        pred = prepare_for_coco_detection(res)
        results.extend(pred)

    print('\n==================== Performance Measurement ====================')
    print('Finished inference on {} images in {:.2f} seconds'.format(
        len(dataloader), inference_time))
    print('=================================================================\n')

    # create bbox detections file
    # following code in https://github.com/aws/aws-neuron-sdk/blob/master/src/examples/
↪tensorflow/yolo_v4_demo/evaluate.ipynb
    resultsfile = modelName + '_bbox_detections.json'
    print('Generating json file...')
    with open(resultsfile, 'w') as f:
        json.dump(results, f)

    # return COCO api object with loadRes
    cocoDt = cocoGt.loadRes(resultsfile)
```

(continues on next page)

(continued from previous page)

```
    return imgIds, cocoDt
```

The next step is to simply load the compiled model from disk and then run inference.

```
[ ]: model_neuron = torch.jit.load('yolo_v4_neuron.pt')
```

```
[ ]: imgIds, cocoDt = run_inference(coco_val_data_loader, orig_coco_val_data_loader, model_
     ↪neuron)
```

We then use the standard `pycocotools` routines to generate a report of bounding box precision/recall.

```
[ ]: from pycocotools.cocoeval import COCOeval

     cocoEval = COCOeval(cocoGt, cocoDt, 'bbox')
     cocoEval.params.imgIds = imgIds
     cocoEval.evaluate()
     cocoEval.accumulate()
     cocoEval.summarize()
```

For reference, we may perform the same evaluation on the CPU model.

```
[ ]: imgIdsRef, cocoDtRef = run_inference(coco_val_data_loader, orig_coco_val_data_loader,␣
     ↪model)
```

```
[ ]: cocoEval = COCOeval(cocoGt, cocoDtRef, 'bbox')
     cocoEval.params.imgIds = imgIdsRef
     cocoEval.evaluate()
     cocoEval.accumulate()
     cocoEval.summarize()
```

8.22.7 Part 5: Benchmark COCO Dataset Performance of the Neuron-Optimized TorchScript

The following code snippet sets up data parallel on 16 NeuronCores and runs saturated multi-threaded inference on the Inferentia accelerator. Note that the number of cores (`n_cores`) should be set to the number of available NeuronCores on the current instance.

```
[ ]: import torch
     import torch.neuron
     import torchvision
     import torchvision.transforms as transforms
     import torchvision.datasets as dset
     import multiprocessing as mp
     from concurrent.futures import ThreadPoolExecutor
     import PIL
     import os
     import time

     n_threads = 16
```

(continues on next page)

(continued from previous page)

```
def get_image_filenames(root=os.getcwd()):
    """
    Generate paths to the coco dataset image files.

    Args:
        root (str): The root folder contains.

    Yields:
        filename (str): The path to an image file.
    """
    image_path = os.path.join(root, 'val2017')
    for root, dirs, files in os.walk(image_path):

8.23 Compiling and Deploying HuggingFace Pretrained BERT

8.23.1 Introduction

In this tutorial we will compile and deploy BERT-base version of HuggingFace Transformers BERT for Inferentia. The full list of HuggingFace's pretrained BERT models can be found in the BERT section on this page https://huggingface.co/transformers/pretrained_models.html.

This Jupyter notebook should be run on an instance which is inf1.6xlarge or larger. The compile part of this tutorial requires inf1.6xlarge and not the inference itself. For simplicity we will run this tutorial on inf1.6xlarge but in real life scenario the compilation should be done on a compute instance and the deployment on inf1 instance to save costs.

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the PyTorch Installation Guide. You can select the kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

Install Dependencies:

This tutorial requires the following pip packages:

- `torch-neuron`
- `neuron-cc[tensorflow]`
- `transformers`

Most of these packages will be installed when configuring your environment using the Neuron PyTorch setup guide. The additional dependencies must be installed here.

```
[ ]: !pip install --upgrade "transformers==4.6.0"
```

8.23.2 Compile the model into an AWS Neuron optimized TorchScript

```
[ ]: import tensorflow  # to workaround a protobuf version conflict issue
import torch
import torch.neuron
from transformers import AutoTokenizer, AutoModelForSequenceClassification, AutoConfig
import transformers
import os
import warnings

# Setting up NeuronCore groups for inf1.6xlarge with 16 cores
num_cores = 16 # This value should be 4 on inf1.xlarge and inf1.2xlarge
os.environ['NEURON_RT_NUM_CORES'] = str(num_cores)

# Build tokenizer and model
tokenizer = AutoTokenizer.from_pretrained("bert-base-cased-finetuned-mrpc")
model = AutoModelForSequenceClassification.from_pretrained("bert-base-cased-finetuned-
↪mrpc", return_dict=False)

# Setup some example inputs
sequence_0 = "The company HuggingFace is based in New York City"
sequence_1 = "Apples are especially bad for your health"
sequence_2 = "HuggingFace's headquarters are situated in Manhattan"

max_length=128
paraphrase = tokenizer.encode_plus(sequence_0, sequence_2, max_length=max_length,␣
↪padding='max_length', truncation=True, return_tensors="pt")
not_paraphrase = tokenizer.encode_plus(sequence_0, sequence_1, max_length=max_length,␣
↪padding='max_length', truncation=True, return_tensors="pt")

# Run the original PyTorch model on compilation exaple
paraphrase_classification_logits = model(**paraphrase)[0]

# Convert example inputs to a format that is compatible with TorchScript tracing
example_inputs_paraphrase = paraphrase['input_ids'], paraphrase['attention_mask'],␣
↪paraphrase['token_type_ids']
example_inputs_not_paraphrase = not_paraphrase['input_ids'], not_paraphrase['attention_
↪mask'], not_paraphrase['token_type_ids']

# Run torch.neuron.trace to generate a TorchScript that is optimized by AWS Neuron
model_neuron = torch.neuron.trace(model, example_inputs_paraphrase)

# Verify the TorchScript works on both example inputs
paraphrase_classification_logits_neuron = model_neuron(*example_inputs_paraphrase)
not_paraphrase_classification_logits_neuron = model_neuron(*example_inputs_not_
↪paraphrase)

# Save the TorchScript for later use
model_neuron.save('bert_neuron.pt')
```

You may inspect `model_neuron.graph` to see which part is running on CPU versus running on the accelerator. All native `aten` operators in the graph will be running on CPU.

```
[ ]: print(model_neuron.graph)
```

8.23.3 Deploy the AWS Neuron optimized TorchScript

To deploy the AWS Neuron optimized TorchScript, you may choose to load the saved TorchScript from disk and skip the slow compilation.

```
[ ]: # Load TorchScript back
model_neuron = torch.jit.load('bert_neuron.pt')
# Verify the TorchScript works on both example inputs
paraphrase_classification_logits_neuron = model_neuron(*example_inputs_paraphrase)
not_paraphrase_classification_logits_neuron = model_neuron(*example_inputs_not_
↪paraphrase)
classes = ['not paraphrase', 'paraphrase']
paraphrase_prediction = paraphrase_classification_logits_neuron[0][0].argmax().item()
not_paraphrase_prediction = not_paraphrase_classification_logits_neuron[0][0].argmax().
↪item()
print('BERT says that "{}" and "{}" are {}'.format(sequence_0, sequence_2,␣
↪classes[paraphrase_prediction]))
print('BERT says that "{}" and "{}" are {}'.format(sequence_0, sequence_1, classes[not_
↪paraphrase_prediction]))
```

Now let's run the model in parallel on four cores

```
[ ]: def get_input_with_padding(batch, batch_size, max_length):
    ## Reformulate the batch into three batch tensors - default batch size batches the␣
↪outer dimension
    encoded = batch['encoded']
    inputs = torch.squeeze(encoded['input_ids'], 1)
    attention = torch.squeeze(encoded['attention_mask'], 1)
    token_type = torch.squeeze(encoded['token_type_ids'], 1)
    quality = list(map(int, batch['quality']))

    if inputs.size()[0] != batch_size:
        print("Input size = {} - padding".format(inputs.size()))
        remainder = batch_size - inputs.size()[0]
        zeros = torch.zeros( [remainder, max_length], dtype=torch.long )
        inputs = torch.cat( [inputs, zeros] )
        attention = torch.cat( [attention, zeros] )
        token_type = torch.cat( [token_type, zeros] )

    assert(inputs.size()[0] == batch_size and inputs.size()[1] == max_length)
    assert(attention.size()[0] == batch_size and attention.size()[1] == max_length)
    assert(token_type.size()[0] == batch_size and token_type.size()[1] == max_length)

    return (inputs, attention, token_type), quality

def count(output, quality):
    assert output.size(0) >= len(quality)
    correct_count = 0
    count = len(quality)
```

(continues on next page)

(continued from previous page)

```
    batch_predictions = [ row.argmax().item() for row in output ]

    for a, b in zip(batch_predictions, quality):
        if int(a)==int(b):
            correct_count += 1

    return correct_count, count
```

8.23.4 Data parallel inference

In the below cell, we use the data parallel approach for inference. In this approach, we load multiple models, all of them running in parallel. Each model is loaded onto a single NeuronCore. In the below implementation, we launch 16 models, thereby utilizing all the 16 cores on an inf1.6xlarge.

> Note: Now if you try to decrease the num_cores in the above cells, please restart the notebook and run `!sudo rmmod neuron; sudo modprobe neuron` step in cell 2 to clear the Neuron cores.

Since, we can run more than 1 model concurrently, the throughput for the system goes up. To achieve maximum gain in throughput, we need to efficiently feed the models so as to keep them busy at all times. In the below setup, this is done by using a producer-consumer model. We maintain a common python queue shared across all the models. The common queue enables feeding data continuously to the models.

[ ]:
```
from parallel import NeuronSimpleDataParallel
from bert_benchmark_utils import BertTestDataset, BertResults
import time
import functools

max_length = 128
num_cores = 16
batch_size = 1

tsv_file="glue_mrpc_dev.tsv"

data_set = BertTestDataset( tsv_file=tsv_file, tokenizer=tokenizer, max_length=max_
↪length )
data_loader = torch.utils.data.DataLoader(data_set, batch_size=batch_size, shuffle=True)

#Result aggregation class (code in bert_benchmark_utils.py)
results = BertResults(batch_size, num_cores)
def result_handler(output, result_id, start, end, input_dict):
    correct_count, inference_count = count(output[0], input_dict.pop(result_id))
    elapsed = end - start
    results.add_result(correct_count, inference_count, [elapsed], [end], [start])

parallel_neuron_model = NeuronSimpleDataParallel('bert_neuron.pt', num_cores)

#Starting the inference threads
parallel_neuron_model.start_continuous_inference()

# Warm up the cores
z = torch.zeros( [batch_size, max_length], dtype=torch.long )
batch = (z, z, z)
```

(continues on next page)

(continued from previous page)

```
for _ in range(num_cores*4):
    parallel_neuron_model.infer(batch, -1, None)

input_dict = {}
input_id = 0
for _ in range(30):
    for batch in data_loader:
        batch, quality = get_input_with_padding(batch, batch_size, max_length)
        input_dict[input_id] = quality
        callback_fn = functools.partial(result_handler, input_dict=input_dict)
        parallel_neuron_model.infer(batch, input_id, callback_fn)
        input_id+=1

# Stop inference
parallel_neuron_model.stop()

with open("benchmark.txt", "w") as f:
    results.report(f, window_size=1)

with open("benchmark.txt", "r") as f:
    for line in f:
        print(line)
```

Now recompile with a larger batch size of six sentence pairs

[ ]:
```
batch_size = 6

example_inputs_paraphrase = (
    torch.cat([paraphrase['input_ids']] * batch_size,0),
    torch.cat([paraphrase['attention_mask']] * batch_size,0),
    torch.cat([paraphrase['token_type_ids']] * batch_size,0)
)

# Run torch.neuron.trace to generate a TorchScript that is optimized by AWS Neuron
model_neuron_batch = torch.neuron.trace(model, example_inputs_paraphrase)

## Save the batched model
model_neuron_batch.save('bert_neuron_b{}.pt'.format(batch_size))
```

Rerun inference with batch 6

[ ]:
```
from parallel import NeuronSimpleDataParallel
from bert_benchmark_utils import BertTestDataset, BertResults
import time
import functools

max_length = 128
num_cores = 16
batch_size = 6

data_set = BertTestDataset( tsv_file=tsv_file, tokenizer=tokenizer, max_length=max_
↪length )
```

(continues on next page)

(continued from previous page)

```
data_loader = torch.utils.data.DataLoader(data_set, batch_size=batch_size, shuffle=True)

#Result aggregation class (code in bert_benchmark_utils.py)
results = BertResults(batch_size, num_cores)
def result_handler(output, result_id, start, end, input_dict):
    correct_count, inference_count = count(output[0], input_dict.pop(result_id))
    elapsed = end - start
    results.add_result(correct_count, inference_count, [elapsed], [end], [start])

parallel_neuron_model = NeuronSimpleDataParallel('bert_neuron_b{}.pt'.format(batch_size),
↪ num_cores)

#Starting the inference threads
parallel_neuron_model.start_continuous_inference()

# Adding to the input queue to warm all cores
z = torch.zeros( [batch_size, max_length], dtype=torch.long )
batch = (z, z, z)
for _ in range(num_cores*4):
    parallel_neuron_model.infer(batch, -1, None)

#Starting the inference threads
parallel_neuron_model.start_continuous_inference()

input_dict = {}
input_id = 0
for _ in range(30):
    for batch in data_loader:
        batch, quality = get_input_with_padding(batch, batch_size, max_length)
        input_dict[input_id] = quality
        callback_fn = functools.partial(result_handler, input_dict=input_dict)
        parallel_neuron_model.infer(batch, input_id, callback_fn)
        input_id+=1

# Stop inference
parallel_neuron_model.stop()

with open("benchmark_b{}.txt".format(batch_size), "w") as f:
    results.report(f, window_size=1)

with open("benchmark_b{}.txt".format(batch_size), "r") as f:
    for line in f:
        print(line)
```

8.24 Deploy a pretrained PyTorch BERT model from HuggingFace on Amazon SageMaker with Neuron container

8.24.1 Overview

In this tutotial we will deploy on SageMaker a pretraine BERT Base model from HuggingFace Transformers, using the AWS Deep Learning Containers. We will use the same model as shown in the Neuron Tutorial "PyTorch - HuggingFace Pretrained BERT Tutorial". We will compile the model and build a custom AWS Deep Learning Container, to include the HuggingFace Transformers Library.

This Jupyter Notebook should run on a ml.c5.4xlarge SageMaker Notebook instance. You can set up your SageMaker Notebook instance by following the Get Started with Amazon SageMaker Notebook Instances documentation.

> We recommend increasing the size of the base root volume of you SM notebook instance, to accomodate the models and containers built locally. A root volume of 10Gb should suffice.

8.24.2 Install Dependencies:

This tutorial requires the following pip packages:

- torch-neuron
- neuron-cc[tensorflow]
- transformers

[ ]:
```
!pip install --upgrade --no-cache-dir torch-neuron neuron-cc[tensorflow] torchvision␣
↪torch --extra-index-url=https://pip.repos.neuron.amazonaws.com
!pip install --upgrade --no-cache-dir 'transformers==4.6.0'
```

8.24.3 Compile the model into an AWS Neuron optimized TorchScript

[ ]:
```
import torch
import torch_neuron

from transformers import AutoTokenizer, AutoModelForSequenceClassification, AutoConfig
```

[ ]:
```
# Build tokenizer and model
tokenizer = AutoTokenizer.from_pretrained("bert-base-cased-finetuned-mrpc")
model = AutoModelForSequenceClassification.from_pretrained("bert-base-cased-finetuned-
↪mrpc", return_dict=False)

# Setup some example inputs
sequence_0 = "The company HuggingFace is based in New York City"
sequence_1 = "Apples are especially bad for your health"
sequence_2 = "HuggingFace's headquarters are situated in Manhattan"

max_length=128
paraphrase = tokenizer.encode_plus(sequence_0, sequence_2, max_length=max_length,␣
↪padding='max_length', truncation=True, return_tensors="pt")
not_paraphrase = tokenizer.encode_plus(sequence_0, sequence_1, max_length=max_length,␣
↪padding='max_length', truncation=True, return_tensors="pt")
```

(continues on next page)

(continued from previous page)

```
# Run the original PyTorch model on compilation exaple
paraphrase_classification_logits = model(**paraphrase)[0]

# Convert example inputs to a format that is compatible with TorchScript tracing
example_inputs_paraphrase = paraphrase['input_ids'], paraphrase['attention_mask'],␣
↪paraphrase['token_type_ids']
example_inputs_not_paraphrase = not_paraphrase['input_ids'], not_paraphrase['attention_
↪mask'], not_paraphrase['token_type_ids']
```

[ ]:
```
%%time
# Run torch.neuron.trace to generate a TorchScript that is optimized by AWS Neuron
# This step may need 3-5 min
model_neuron = torch.neuron.trace(model, example_inputs_paraphrase, verbose=1, compiler_
↪workdir='./compilation_artifacts')
```

You may inspect **model_neuron.graph** to see which part is running on CPU versus running on the accelerator. All native **aten** operators in the graph will be running on CPU.

[ ]:
```
# See  which part is running on CPU versus running on the accelerator.
print(model_neuron.graph)
```

Save the compiled model, so it can be packaged and sent to S3.

[ ]:
```
# Save the TorchScript for later use
model_neuron.save('neuron_compiled_model.pt')
```

Package the pre-trained model and upload it to S3

To make the model available for the SageMaker deployment, you will TAR the serialized graph and upload it to the default Amazon S3 bucket for your SageMaker session.

[ ]:
```
# Now you'll create a model.tar.gz file to be used by SageMaker endpoint
!tar -czvf model.tar.gz neuron_compiled_model.pt
```

[ ]:
```
import boto3
import time
from sagemaker.utils import name_from_base
import sagemaker
```

[ ]:
```
# upload model to S3
role = sagemaker.get_execution_role()
sess=sagemaker.Session()
region=sess.boto_region_name
bucket=sess.default_bucket()
sm_client=boto3.client('sagemaker')
```

[ ]:
```
model_key = '{}/model/model.tar.gz'.format('inf1_compiled_model')
model_path = 's3://{}/{}'.format(bucket, model_key)
boto3.resource('s3').Bucket(bucket).upload_file('model.tar.gz', model_key)
```

(continues on next page)

(continued from previous page)

```
print("Uploaded model to S3:")
print(model_path)
```

8.24.4 Build and Push the container

The following shell code shows how to build the container image using docker build and push the container image to ECR using docker push. The Dockerfile in this example is available in the **container** folder. Here's an example of the Dockerfile:

```
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-inference-neuron:1.7.1-neuron-
↪py36-ubuntu18.04

# Install packages
RUN pip install "transformers==4.7.0"
```

[ ]:
```
!cat container/Dockerfile
```

Before running the next cell, make sure your SageMaker IAM role has access to ECR. If not, you can attache the role `AmazonEC2ContainerRegistryPowerUser` to your IAM role ARN, which allows you to upload image layers to ECR.

It takes 5 minutes to build docker images and upload image to ECR

[ ]:
```
%%sh

# The name of our algorithm
algorithm_name=neuron-py36-inference

cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none␣
↪defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.

aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1

if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR in order to pull down the SageMaker PyTorch image
aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-
↪stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
```

(continues on next page)

(continued from previous page)

```
# Build the docker image locally with the image name and then push it to ECR
# with the full name.
docker build  -t ${algorithm_name} . --build-arg REGION=${region}
docker tag ${algorithm_name} ${fullname}

# Get the login command from ECR and execute it directly
aws ecr get-login-password --region ${region} | docker login --username AWS --password-
↪stdin ${account}.dkr.ecr.${region}.amazonaws.com
docker push ${fullname}
```

8.24.5 Deploy Container and run inference based on the pretrained model

To deploy a pretrained PyTorch model, you'll need to use the PyTorch estimator object to create a PyTorchModel object and set a different entry_point.

You'll use the PyTorchModel object to deploy a PyTorchPredictor. This creates a SageMaker Endpoint – a hosted prediction service that we can use to perform inference.

[ ]:
```
import sys

!{sys.executable} -m pip install Transformers
```

[ ]:
```
import os
import boto3
import sagemaker

role = sagemaker.get_execution_role()
sess = sagemaker.Session()

bucket = sess.default_bucket()
prefix = "inf1_compiled_model/model"

# Get container name in ECR
client=boto3.client('sts')
account=client.get_caller_identity()['Account']

my_session=boto3.session.Session()
region=my_session.region_name

algorithm_name="neuron-py36-inference"
ecr_image='{}.dkr.ecr.{}.amazonaws.com/{}:latest'.format(account, region, algorithm_name)
print(ecr_image)
```

An implementation of *model_fn* is required for inference script. We are going to implement our own **model_fn** and **predict_fn** for Hugging Face Bert, and use default implementations of **input_fn** and **output_fn** defined in sagemaker-pytorch-containers.

In this example, the inference script is put in **code** folder. Run the next cell to see it:

[ ]:
```
!pygmentize code/inference.py
```

Path of compiled pretrained model in S3:

[ ]:
```
key = os.path.join(prefix, "model.tar.gz")
pretrained_model_data = "s3://{}/{}".format(bucket, key)
print(pretrained_model_data)
```

The model object is defined by using the SageMaker Python SDK's PyTorchModel and pass in the model from the estimator and the entry_point. The endpoint's entry point for inference is defined by model_fn as seen in the previous code block that prints out **inference.py**. The model_fn function will load the model and required tokenizer.

Note, **image_uri** must be user's own ECR images.

[ ]:
```
from sagemaker.pytorch.model import PyTorchModel

pytorch_model = PyTorchModel(
    model_data=pretrained_model_data,
    role=role,
    source_dir="code",
    framework_version="1.7.1",
    entry_point="inference.py",
    image_uri=ecr_image
)

# Let SageMaker know that we've already compiled the model via neuron-cc
pytorch_model._is_compiled_model = True
```

The arguments to the deploy function allow us to set the number and type of instances that will be used for the Endpoint.

Here you will deploy the model to a single **ml.inf1.2xlarge** instance. It may take 6-10 min to deploy.

[ ]:
```
%%time

predictor = pytorch_model.deploy(initial_instance_count=1, instance_type="ml.inf1.2xlarge
↪")
```

[ ]:
```
print(predictor.endpoint_name)
```

Since in the input_fn we declared that the incoming requests are json-encoded, we need to use a json serializer, to encode the incoming data into a json string. Also, we declared the return content type to be json string, we Need to use a json deserializer to parse the response.

[ ]:
```
predictor.serializer = sagemaker.serializers.JSONSerializer()
predictor.deserializer = sagemaker.deserializers.JSONDeserializer()
```

Using a list of sentences, now SageMaker endpoint is invoked to get predictions.

[ ]:
```
%%time
result = predictor.predict(
    [
        "Never allow the same bug to bite you twice.",
        "The best part of Amazon SageMaker is that it makes machine learning easy.",
    ]
)
print(result)
```

[ ]:
```
%%time
result = predictor.predict(
    [
        "The company HuggingFace is based in New York City",
        "HuggingFace's headquarters are situated in Manhattan",
    ]
)
print(result)
```

8.24.6 Benchmarking your endpoint

The following cells create a load test for your endpoint. You first define some helper functions: `inference_latency` runs the endpoint request, collects cliend side latency and any errors, `random_sentence` builds random to be sent to the endpoint.

[ ]:
```
import numpy as np
import datetime
import math
import time
import boto3
import matplotlib.pyplot as plt
from joblib import Parallel, delayed
import numpy as np
from tqdm import tqdm
import random
```

[ ]:
```
def inference_latency(model,*inputs):
    """
    infetence_time is a simple method to return the latency of a model inference.

        Parameters:
            model: torch model onbject loaded using torch.jit.load
            inputs: model() args

        Returns:
            latency in seconds
    """
    error = False
    start = time.time()
    try:
        results = model(*inputs)
    except:
        error = True
        results = []
    return {'latency':time.time() - start, 'error': error, 'result': results}
```

[ ]:
```
def random_sentence():

    s_nouns = ["A dude", "My mom", "The king", "Some guy", "A cat with rabies", "A sloth
↪", "Your homie", "This cool guy my gardener met yesterday", "Superman"]
    p_nouns = ["These dudes", "Both of my moms", "All the kings of the world", "Some guys
↪", "All of a cattery's cats", "The multitude of sloths living under your bed", "Your
↪homies", "Like, these, like, all these people", "Supermen"]
```

(continues on next page)

(continued from previous page)

```
    s_verbs = ["eats", "kicks", "gives", "treats", "meets with", "creates", "hacks",
↪"configures", "spies on", "retards", "meows on", "flees from", "tries to automate",
↪"explodes"]
    p_verbs = ["eat", "kick", "give", "treat", "meet with", "create", "hack", "configure
↪", "spy on", "retard", "meow on", "flee from", "try to automate", "explode"]
    infinitives = ["to make a pie.", "for no apparent reason.", "because the sky is␣
↪green.", "for a disease.", "to be able to make toast explode.", "to know more about␣
↪archeology."]

    return (random.choice(s_nouns) + ' ' + random.choice(s_verbs) + ' ' + random.
↪choice(s_nouns).lower() or random.choice(p_nouns).lower() + ' ' + random.
↪choice(infinitives))

print([random_sentence(), random_sentence()])
```

The following cell creates `number_of_clients` concurrent threads to run `number_of_runs` requests. Once completed, a `boto3` CloudWatch client will query for the server side latency metrics for comparison.

[ ]:
```
# Defining Auxiliary variables
number_of_clients = 2
number_of_runs = 1000
t = tqdm(range(number_of_runs),position=0, leave=True)

# Starting parallel clients
cw_start = datetime.datetime.utcnow()

results = Parallel(n_jobs=number_of_clients,prefer="threads")(delayed(inference_
↪latency)(predictor.predict,[random_sentence(), random_sentence()]) for mod in t)
avg_throughput = t.total/t.format_dict['elapsed']

cw_end = datetime.datetime.utcnow()

# Computing metrics and print
latencies = [res['latency'] for res in results]
errors = [res['error'] for res in results]
error_p = sum(errors)/len(errors) *100
p50 = np.quantile(latencies[-1000:],0.50) * 1000
p90 = np.quantile(latencies[-1000:],0.95) * 1000
p95 = np.quantile(latencies[-1000:],0.99) * 1000

print(f'Avg Throughput: :{avg_throughput:.1f}\n')
print(f'50th Percentile Latency:{p50:.1f} ms')
print(f'90th Percentile Latency:{p90:.1f} ms')
print(f'95th Percentile Latency:{p95:.1f} ms\n')
print(f'Errors percentage: {error_p:.1f} %\n')

# Querying CloudWatch
print('Getting Cloudwatch:')
cloudwatch = boto3.client('cloudwatch')
statistics=['SampleCount', 'Average', 'Minimum', 'Maximum']
extended=['p50', 'p90', 'p95', 'p100']
```

(continues on next page)

(continued from previous page)

```
# Give 5 minute buffer to end
cw_end += datetime.timedelta(minutes=5)

# Period must be 1, 5, 10, 30, or multiple of 60
# Calculate closest multiple of 60 to the total elapsed time
factor = math.ceil((cw_end - cw_start).total_seconds() / 60)
period = factor * 60
print('Time elapsed: {} seconds'.format((cw_end - cw_start).total_seconds()))
print('Using period of {} seconds\n'.format(period))

cloudwatch_ready = False
# Keep polling CloudWatch metrics until datapoints are available
while not cloudwatch_ready:
  time.sleep(30)
  print('Waiting 30 seconds ...')
  # Must use default units of microseconds
  model_latency_metrics = cloudwatch.get_metric_statistics(MetricName='ModelLatency',
                                                Dimensions=[{'Name': 'EndpointName',
                                                             'Value': predictor.endpoint_
↪name},
                                                            {'Name': 'VariantName',
                                                             'Value': "AllTraffic"}],
                                                Namespace="AWS/SageMaker",
                                                StartTime=cw_start,
                                                EndTime=cw_end,
                                                Period=period,
                                                Statistics=statistics,
                                                ExtendedStatistics=extended
                                                )
  # Should be 1000
  if len(model_latency_metrics['Datapoints']) > 0:
    print('{} latency datapoints ready'.format(model_latency_metrics['Datapoints'][0][
↪'SampleCount']))
    side_avg = model_latency_metrics['Datapoints'][0]['Average'] / number_of_runs
    side_p50 = model_latency_metrics['Datapoints'][0]['ExtendedStatistics']['p50'] /␣
↪number_of_runs
    side_p90 = model_latency_metrics['Datapoints'][0]['ExtendedStatistics']['p90'] /␣
↪number_of_runs
    side_p95 = model_latency_metrics['Datapoints'][0]['ExtendedStatistics']['p95'] /␣
↪number_of_runs
    side_p100 = model_latency_metrics['Datapoints'][0]['ExtendedStatistics']['p100'] /␣
↪number_of_runs

    print(f'50th Percentile Latency:{side_p50:.1f} ms')
    print(f'90th Percentile Latency:{side_p90:.1f} ms')
    print(f'95th Percentile Latency:{side_p95:.1f} ms\n')

    cloudwatch_ready = True
```

Cleanup

Endpoints should be deleted when no longer in use, to avoid costs.

[ ]:
```
predictor.delete_endpoint(predictor.endpoint)
```

[ ]:
```

```

8.25 Transformers MarianMT Tutorial

In this tutorial, you will deploy the HuggingFace MarianMT model for text translation.

This Jupyter notebook should be run on an inf1.6xlarge instance since you will be loading and compiling several large models.

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the PyTorch Installation Guide. You can select the kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

To generate text, you will be using the beam search algorithm to incrementally generate token candidates until the full output text has been created. Unlike simple single-pass models, this algorithm divides the work into two distinct phases:

- **Encoder**: Convert the input text into an encoded representation. (Executed once)
- **Decoder**: Use the encoded representation of the input text and the current output tokens to incrementally generate the set of next best candidate tokens. (Executed many times)

In this tutorial you will perform the following steps:

- **Compile**: Compile both the Encoder and Decoder for Neuron using simplified interfaces for inference.
- **Infer**: Run on CPU and Neuron and compare results.

8.25.1 Install Dependencies:

This tutorial has the following dependencies:

- `transformers==4.0.1`
- `torch-neuron==1.7.*`
- `sentencepiece`
- `neuron-cc[tensorflow]`

The following will install the required `transformers` version. Note that encoder/decoder API changes across different minor versions requires that you are specific about the version used. Also note that the `torch-neuron` version is pinned due to `transformer` compatibility issues.

[ ]:
```
!pip install --force-reinstall --extra-index-url=https://pip.repos.neuron.amazonaws.com
↪"torch-neuron==1.7.*" "transformers==4.0.1" "protobuf<4" sentencepiece "neuron-
↪cc[tensorflow]"
```

8.25.2 Parameters

The parameters of a generative model can be tuned for different use-cases. In this example, you'll tailor the parameters to a single inference beam search for an on-demand inference use-case. See the MarianConfig for parameter details.

Rather than varying the encoder/decoder token sizes at runtime, you must define these parameters prior to compilation. The encoder/decoder token sizes are important tunable parameters as a large token sequence will offer greater sentence length flexibility but perform worse than a small token sequence.

To maximize performance on Neuron, the `num_beams`, `max_encode_length` and `max_decoder_length` should be made as small as possible for the use-case.

For this tutorial you will use a model that translates sentences of up to 32 token from English to German.

[ ]:
```
model_name = "Helsinki-NLP/opus-mt-en-de" # English -> German model
num_texts = 1                              # Number of input texts to decode
num_beams = 4                              # Number of beams per input text
max_encoder_length = 32                    # Maximum input token length
max_decoder_length = 32                    # Maximum output token length
```

8.25.3 Imports

On text generation tasks, HuggingFace Transformers defines a GenerationMixin base class which provides standard methods and algorithms to generate text. For this tutorial, you will be using the beam search algorithm on encoder/decoder architectures.

To be able to use these methods, you will be defining your own class derived from the GenerationMixin class to run a beam search. This will invoke the encoder and decoder layers in a way that is compatible with fixed sized inputs and traced modules. This means you must import the base class and the output objects (Seq2SeqLMOutput, BaseModelOutput) used by the beam_search algorithm.

[ ]:
```
import os

import torch
import numpy as np
from torch.nn import functional as F

from transformers import MarianMTModel, MarianTokenizer, MarianConfig
from transformers.generation_utils import GenerationMixin
from transformers.modeling_outputs import Seq2SeqLMOutput, BaseModelOutput
from transformers.modeling_utils import PreTrainedModel

import torch_neuron
```

8.25.4 CPU Model Execution

Start by executing the model on CPU to test its execution.

The following defines the inference function which will be used to compare the Neuron and CPU output. In this example you will display all beam search sequences that were generated. On a real on-demand use case, set the `num_return_sequences` to 1 to return only the top result.

[ ]:
```
def infer(model, tokenizer, text):

    # Truncate and pad the max length to ensure that the token size is compatible with␣
↪fixed-sized encoder (Not necessary for pure CPU execution)
    batch = tokenizer(text, max_length=max_decoder_length, truncation=True, padding='max_
↪length', return_tensors="pt")
    output = model.generate(**batch, max_length=max_decoder_length, num_beams=num_beams,␣
↪num_return_sequences=num_beams)
    results = [tokenizer.decode(t, skip_special_tokens=True) for t in output]

    print('Texts:')
    for i, summary in enumerate(results):
        print(i + 1, summary)
```

[ ]:
```
model_cpu = MarianMTModel.from_pretrained(model_name)
model_cpu.eval()

tokenizer_cpu = MarianTokenizer.from_pretrained(model_name)

sample_text = "I am a small frog."
```

[ ]:
```
infer(model_cpu, tokenizer_cpu, sample_text)
```

8.25.5 Encoder & Decoder Modules

Here you will define wrappers around the encoder and decoder portions of the generation model that are compatible with `torch.jit.trace` as well as fixed-sized inputs.

Important features which are distinct from the default configuration:

1. A fixed sized `causal_mask` in the `NeuronDecoder` rather than varying the size for each iteration. This is because Neuron requires padded `input_ids` input rather than the default behavior where this grows for each beam search iteration.
2. Disabled `return_dict`. When this is enabled, the network uses `dataclass` type outputs which are not compatible with `torch.jit.trace`.
3. Disabled `use_cache`. When this option is enabled, the network expects a collection of cache tensors which grow upon each iteration. Since Neuron requires fixed sized inputs, this must be disabled.
4. The `GenerationMixin:beam_search` implementation uses only the logits for the current iteration index from the original decoder layer output. Since inputs are padded, performance can be improved by selecting only a subset of the hidden state prior to the final linear layer. For efficiency on Neuron, this reduction (`reduce`) uses an elementwise-multiply to mask out the unused hidden values and then sums along an axis.
5. Since a reduction step is insterted between the decoder output and the final logit calculation, the original `model` attribute is not used. Instead the `NeuronDecoder` class combines the decoder, reducer, and linear layers into a combined forward pass. In the original model there is a clear distinction between the decoder layer and the final linear layer. These layers are fused together to get one large fully optimized graph.

[ ]:
```
def reduce(hidden, index):
    _, n_length, _ = hidden.shape
```

(continues on next page)

(continued from previous page)

```
    # Create selection mask
    mask = torch.arange(n_length, dtype=torch.float32) == index
    mask = mask.view(1, -1, 1)

    # Broadcast mask
    masked = torch.multiply(hidden, mask)

    # Reduce along 1st dimension
    summed = torch.sum(masked, 1)
    return torch.unsqueeze(summed, 1)

class NeuronEncoder(torch.nn.Module):

    def __init__(self, model):
        super().__init__()
        self.encoder = model.model.encoder

    def forward(self, input_ids, attention_mask):
        return self.encoder(input_ids, attention_mask=attention_mask, return_dict=False)

class NeuronDecoder(torch.nn.Module):

    def __init__(self, model, max_length):
        super().__init__()
        self.weight = model.model.shared.weight.clone().detach()
        self.bias = model.final_logits_bias.clone().detach()
        self.decoder = model.model.decoder
        self.max_length = max_length

    def forward(self, input_ids, attention_mask, encoder_outputs, index):

        # Build a fixed sized causal mask for the padded decoder input ids
        mask = np.triu(np.ones((self.max_length, self.max_length)), 1)
        mask[mask == 1] = -np.inf
        causal_mask = torch.tensor(mask, dtype=torch.float)

        # Invoke the decoder
        hidden, = self.decoder(
            input_ids=input_ids,
            encoder_hidden_states=encoder_outputs,
            encoder_padding_mask=attention_mask,
            decoder_padding_mask=None,
            decoder_causal_mask=causal_mask,
            return_dict=False,
            use_cache=False,
        )

        # Reduce decoder outputs to the specified index (current iteration)
        hidden = reduce(hidden, index)
```

(continues on next page)

(continued from previous page)

```
        # Compute final linear layer for token probabilities
        logits = F.linear(
            hidden,
            self.weight,
            bias=self.bias
        )
        return logits
```

8.25.6 GenerationMixin Class

To be able to use `GenerationMixin:beam_search` you must define your own class implementation that invokes the traced `NeuronEncoder` and `NeuronDecoder` modules. The standard generator model implementation will not work by default because it is not designed to invoke the traced models with padded inputs.

Below, the `NeuronGeneration:trace` method uses the loaded generator model and traces both the Encoder and Decoder.

Next, the following methods are copied directly from the to the original class to ensure that inference behavior is identical: - `adjust_logits_during_generation` - `_force_token_id_to_be_generated`

To invoke the Encoder and Decoder traced modules in a way that is compatible with the `GenerationMixin:beam_search` implementation, the `get_encoder`, `__call__`, and `prepare_inputs_for_generation` methods are overriden.

Lastly, the class defines methods for serialization so that the model can be easily saved and loaded.

```
[ ]: class NeuronGeneration(PreTrainedModel, GenerationMixin):

         def trace(self, model, num_texts, num_beams, max_encoder_length, max_decoder_length):
             """
             Traces the encoder and decoder modules for use on Neuron.

             This function fixes the network to the given sizes. Once the model has been
             compiled to a given size, the inputs to these networks must always be of
             fixed size.

             Args:
                 model (GenerationMixin): The transformer-type generator model to trace
                 num_texts (int): The number of input texts to translate at once
                 num_beams (int): The number of beams to computer per text
                 max_encoder_length (int): The maximum number of encoder tokens
                 max_encoder_length (int): The maximum number of decoder tokens
             """
             self.config.max_decoder_length = max_decoder_length

             # Trace the encoder
             inputs = (
                 torch.ones((num_texts, max_encoder_length), dtype=torch.long),
                 torch.ones((num_texts, max_encoder_length), dtype=torch.long),
             )
             encoder = NeuronEncoder(model)
             self.encoder = torch_neuron.trace(encoder, inputs)
```

(continues on next page)

(continued from previous page)

```
        # Trace the decoder (with expanded inputs)
        batch_size = num_texts * num_beams
        inputs = (
            torch.ones((batch_size, max_decoder_length), dtype=torch.long),
            torch.ones((batch_size, max_encoder_length), dtype=torch.long),
            torch.ones((batch_size, max_encoder_length, model.config.d_model),␣
↪dtype=torch.float),
            torch.tensor(0),
        )
        decoder = NeuronDecoder(model, max_decoder_length)
        self.decoder = torch_neuron.trace(decoder, inputs)

    # ----------------------------------------------------------------------
    # Beam Search Methods (Copied directly from transformers)
    # ----------------------------------------------------------------------

            attention_mask=attention_mask,
            encoder_outputs=encoder_outputs.last_hidden_state,
            current_length=torch.tensor(current_length - 1),
        )

    def get_encoder(self):
        """Helper to invoke the encoder and wrap the results in the expected structure"""
        def encode(input_ids, attention_mask, **kwargs):
            output, = self.encoder(input_ids, attention_mask)
```

(continues on next page)

(continued from previous page)

```
            return BaseModelOutput(
                last_hidden_state=output,
            )
        return encode

    def __call__(self, input_ids, attention_mask, encoder_outputs, current_length,␣
↪**kwargs):
        """Helper to invoke the decoder and wrap the results in the expected structure"""
        logits = self.decoder(input_ids, attention_mask, encoder_outputs, current_length)
        return Seq2SeqLMOutput(logits=logits)

    # ----------------------------------------------------------------------
    # Serialization
    # ----------------------------------------------------------------------

    def save_pretrained(self, directory):
        if os.path.isfile(directory):
            print(f"Provided path ({directory}) should be a directory, not a file")
            return
        os.makedirs(directory, exist_ok=True)
        torch.jit.save(self.encoder, os.path.join(directory, 'encoder.pt'))
        torch.jit.save(self.decoder, os.path.join(directory, 'decoder.pt'))
        self.config.save_pretrained(directory)

    @classmethod
    def from_pretrained(cls, directory):
        config = MarianConfig.from_pretrained(directory)
        obj = cls(config)
        obj.encoder = torch.jit.load(os.path.join(directory, 'encoder.pt'))
        obj.decoder = torch.jit.load(os.path.join(directory, 'decoder.pt'))
        return obj

    @property
    def device(self):
        return torch.device('cpu')
```

8.25.7 Execution

Using everything together from above, now the process to deploy the model is as follows:

1. Compile the model
2. Serialize an artifact
3. Load the serialized artifact
4. Execute the model Neuron

[ ]:
```
# This is the name of the folder where the artifacts will be stored on disk
neuron_name = 'NeuronMarianMT'
```

[ ]:
```
model_neuron = NeuronGeneration(model_cpu.config)

# 1. Compile the model
# Note: This may take a couple of minutes since both the encoder/decoder will be compiled
model_neuron.trace(
    model=model_cpu,
    num_texts=num_texts,
    num_beams=num_beams,
    max_encoder_length=max_encoder_length,
    max_decoder_length=max_decoder_length,
)

# 2. Serialize an artifact
# After this call you will have an `encoder.pt`, `decoder.pt` and `config.json` in the␣
↪neuron_name folder
model_neuron.save_pretrained(neuron_name)
```

[ ]:
```

# 3. Load the serialized artifact
model_neuron = NeuronGeneration.from_pretrained(neuron_name)
```

[ ]:
```
# 4. Execute the model Neuron
infer(model_neuron, tokenizer_cpu, sample_text)
```

Comparing the Neuron execution to the original CPU implementation, you will see the exact same generated text.

[ ]:
```
# CPU execution for comparison
infer(model_cpu, tokenizer_cpu, sample_text)
```

8.25.8 Appendix - BART (Mask Filling Task)

These `NeuronGeneration` class can be applied to the BART model for the task of filling in mask tokens.

[ ]:
```
from transformers import BartForConditionalGeneration, BartTokenizer
bart_name = "facebook/bart-large"
bart_model = BartForConditionalGeneration.from_pretrained(bart_name, force_bos_token_to_
↪be_generated=True)
bart_tokenizer = BartTokenizer.from_pretrained(bart_name)
bart_text = "UN Chief Says There Is No <mask> in Syria"
```

[ ]:
```
# CPU Execution
infer(bart_model, bart_tokenizer, bart_text)
```

[ ]:
```
# Neuron Execution
bart_neuron = NeuronGeneration(bart_model.config)
bart_neuron.trace(
    model=bart_model,
    num_texts=num_texts,
```

(continues on next page)

(continued from previous page)

```
    num_beams=num_beams,
    max_encoder_length=max_encoder_length,
    max_decoder_length=max_decoder_length,
)
infer(bart_neuron, bart_tokenizer, bart_text)
```

8.25.9 Appendix - Pegasus (Summarization Task)

These `NeuronGeneration` class can be applied to the Pegasus model for summarization.

```
[ ]: from transformers import PegasusForConditionalGeneration, PegasusTokenizer
pegasus_name = 'google/pegasus-xsum'
pegasus_model = PegasusForConditionalGeneration.from_pretrained(pegasus_name)
pegasus_tokenizer = PegasusTokenizer.from_pretrained(pegasus_name)
pegasus_text = "PG&E stated it scheduled the blackouts in response to forecasts for high␣
↪winds amid dry conditions. The aim is to reduce the risk of wildfires."
```

```
[ ]: # CPU Execution
infer(pegasus_model, pegasus_tokenizer, pegasus_text)
```

```
[ ]: # Neuron Execution
pegasus_neuron = NeuronGeneration(pegasus_model.config)
pegasus_neuron.trace(
    model=pegasus_model,
    num_texts=num_texts,
    num_beams=num_beams,
    max_encoder_length=max_encoder_length,
    max_decoder_length=max_decoder_length,
)
infer(pegasus_neuron, pegasus_tokenizer, pegasus_text)
```

Utilizing Neuron Capabilities Tutorials

- BERT TorchServe tutorial [html]
- NeuronCore Pipeline tutorial *[html]* [notebook]

8.26 Using NeuronCore Pipeline with PyTorch

In this tutorial you compile a pretrained BERT base model from HuggingFace Transformers, using the NeuronCore Pipeline feature of the AWS Neuron SDK. You benchmark model latency of the pipeline parallel mode and compare with the usual data parallel (multi-worker) deployment.

This tutorial is intended to run in an inf1.6xlarge, running the latest AWS Deep Learning AMI (DLAMI). The inf1.6xlarge instance size has AWS Inferentia chips for a total of 16 NeuronCores.

Verify that this Jupyter notebook is running the Python or Conda kernel environment that was set up according to the PyTorch Installation Guide. You can select the kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

Note: Do not execute this tutorial using "Run -> Run all cells" option.

8.26.1 Install Dependencies:

This tutorial requires the following pip packages:

- `torch-neuron`
- `neuron-cc[tensorflow]`
- `transformers`

Most of these packages will be installed when configuring your environment using the Neuron PyTorch setup guide. The additional HuggingFace Transformers dependency must be installed here.

[ ]:
```
!pip install --upgrade "transformers==4.6.0"
```

8.26.2 Compiling a BERT base model for a single NeuronCore

To run a HuggingFace BERTModel on Inferentia, you only need to add a single extra line of code to the usual Transformers PyTorch implementation, after importing the torch_neuron framework.

Add the argument `return_dict=False` to the BERT transformers model so it can be traced with TorchScript. TorchScript is a way to create serializable and optimizable models from PyTorch code.

Enable padding to a maximum sequence length of 128, to test the model's performance with a realistic payload size. You can adapt this sequence length to your application's requirement.

You can adapt the original example on the BertModel forward pass docstring according to the following cell

[ ]:
```
import torch
import torch_neuron
from transformers import BertTokenizer, BertModel

from joblib import Parallel, delayed
import numpy as np
from tqdm import tqdm

import os
import time

tokenizer = BertTokenizer.from_pretrained('bert-base-uncased')
model = BertModel.from_pretrained('bert-base-uncased',return_dict=False)

inputs = tokenizer("Hello, my dog is cute",return_tensors="pt",max_length=128,padding=
↪'max_length',truncation=True)
```

The one extra line required is the call to torch.neuron.trace() method. This call compiles the model and returns the forwad method of the torch `nn.Model` method, which you can use to run inference.

The compiled graph can be saved using the `torch.jit.save` function and restored using `torch.jit.load` function for inference on Inf1 instances. During inference, the previously compiled artifacts will be loaded into the Neuron Runtime for inference execution.

```
[ ]: neuron_model = torch.neuron.trace(model,
                                       example_inputs = (inputs['input_ids'],inputs[
↪'attention_mask']),
                                       verbose=1)
```

8.26.3 Running the BERT base model on a single NeuronCore

With the model already available in memory, you can time one execution and check for the latency on the single inference call. You will load the model into Inferentia with a single inference call. A large "wall time" is expected when you first run the next cell, running the cell twice will show the actual inference latency:

```
[ ]: %%time
# The following line tests inference and should be executed on Inf1 instance family.
outputs = neuron_model(*(inputs['input_ids'],inputs['attention_mask']))
```

You can also check for the throughput of the single model running on a single NeuronCore.

The sequential inference test (for loop) does not measure all the performance one can achieve in an instance with multiple NeuronCores. To improve hardwar utilization you can run parallel inference requests over multiple model workers, which you'll test in the Data Parallel Bonus Section below.

```
[ ]: %%time
for _ in tqdm(range(100)):
    outputs = neuron_model(*(inputs['input_ids'],inputs['attention_mask']))
```

Save the compiled model for later use:

```
[ ]: neuron_model.save('bert-base-uncased-neuron.pt')
```

8.26.4 Compiling a BERT base model for 16 NeuronCores

Our next step is to compile the same model for all 16 NeuronCores available in the inf1.6xlarge and check the performance difference when running pipeline parallel inferences..

Prior to compiling and executing the model, use the following cell to restart your IPython Kernel.

> **Note:** If you run this notebook using Jupyter Notebooks, instead of Jupyterlab, you may need to restart the kernel using the "Kernel -> Restart" option, after running the next cell

```
[ ]: import IPython
# Automatically restarts kernel
IPython.Application.instance().kernel.do_shutdown(True)
```

After you get `{'status': 'ok', 'restart': True}`, reinstantiate your environment with the required libraries and the `BertTokenizer` and `BertModel` from Transformers.

```
[ ]: import torch
import torch_neuron
from transformers import BertTokenizer, BertModel

from joblib import Parallel, delayed
```

(continues on next page)

(continued from previous page)

```
import numpy as np
from tqdm import tqdm

import os
import time

tokenizer = BertTokenizer.from_pretrained('bert-base-uncased')
model = BertModel.from_pretrained('bert-base-uncased',return_dict=False)

inputs = tokenizer("Hello, my dog is cute",return_tensors="pt",max_length=128,padding=
↪'max_length',truncation=True)
```

To enable pipeline mode during compilation, you need only to add the compiler flag `--neuroncore-pipeline-cores` and set the number of desired cores. The cell below sets up a `neuroncore_pipeline_cores` string, which you can set for the available number of NeuronCores on the instance: *inf1.6xlarge* has 16 NeuronCores in 4 Inferentia chips.

[ ]:
```
# Number of Cores in the Pipeline Mode
neuroncore_pipeline_cores = 16 # This string should be '4' on an inf1.xlarge

# Compiling for neuroncore-pipeline-cores='16'
neuron_pipeline_model = torch.neuron.trace(model,
                                           example_inputs = (inputs['input_ids'],inputs[
↪'attention_mask']),
                                           verbose=1,
                                           compiler_args = ['--neuroncore-pipeline-cores
↪', str(neuroncore_pipeline_cores)]
                                          )
```

8.26.5 Running the BERT base model on 16 NeuronCores

Next, time one execution and check for the latency on the single inference call over 16 cores. You will load the model into Inferentia with a single inference call. A large "wall time" is expected when you first run the next cell, running the cell twice will show the actual inference latency:

[ ]:
```
%%time
# The following line tests inference and should be executed on Inf1 instance family.
outputs = neuron_pipeline_model(*(inputs['input_ids'],inputs['attention_mask']))
```

Check also for the throughput of the single model running over a 16 NeuronCores.

The sequential inference test (for loop) does not measure all the performance one can achieve with Pipeline mode. As the inference runs in streaming fashion, at least 15 cores are waiting for a new call until the last one processes the first call. This results in low NeuronCore utilization. To improve hardware utilization you will require parallel inference requests, which you'll test in the next section.

[ ]:
```
for _ in tqdm(range(100)):
    outputs = neuron_pipeline_model(*(inputs['input_ids'],inputs['attention_mask']))
```

8.26.6 Load Testing the Pipeline Parallel Mode

To put the 16 NeuronCores group to test, a client has to run concurrent requests to the model. In this Notebook setup you achieve it by creating a thread pool with `Joblib.Parallel`, with all workers on the pool runing one inference call.

You can define a new method called `inference_latency()` so that you measure the amount of time each inference calls take.

[ ]:
```
def inference_latency(model,*inputs):
    """
    infetence_time is a simple method to return the latency of a model inference.

        Parameters:
            model: torch model onbject loaded using torch.jit.load
            inputs: model() args

        Returns:
            latency in seconds
    """
    start = time.time()
    _ = model(*inputs)
    return time.time() - start
```

Use `tqdm` to measure total throughput of your experiment, with a nice side-effect of "cool progress bar!". The total throughput is expected to be high, so set your experiment range to a large number, here 30k inferences.

To calculate the latency statistics over the returned 30k list of latencies use `numpy.qunatile()` method.

[ ]:
```
t = tqdm(range(30000), position=0, leave=True)
latency = Parallel(n_jobs=12,prefer="threads")(delayed(inference_latency)(neuron_
↪pipeline_model,*(inputs['input_ids'],inputs['attention_mask'])) for i in t)

p50 = np.quantile(latency[-10000:],0.50) * 1000
p95 = np.quantile(latency[-10000:],0.95) * 1000
p99 = np.quantile(latency[-10000:],0.99) * 1000
avg_throughput = t.total/t.format_dict['elapsed']
print(f'Avg Throughput: :{avg_throughput:.1f}')
print(f'50th Percentile Latency:{p50:.1f} ms')
print(f'95th Percentile Latency:{p95:.1f} ms')
print(f'99th Percentile Latency:{p99:.1f} ms')
```

Save compile model for later use:

[ ]:
```
# Save the TorchScript graph
neuron_pipeline_model.save('bert-base-uncased-neuron-pipeline.pt')
```

8.26.7 Bonus Section - Load Testing Data Parallel Mode

Prior to setting up a Data Parallel experiment using the model compiled for a single NeuronCore, run the following cell to restart your IPython Kernel.

> **Note:** If you run this notebook using Jupyter Notebooks, instead of Jupyterlab, you may need to restart the kernel using the "Kernel -> Restart" option, after running the next cell

[ ]:
```
import IPython
# Automatically restarts kernel
IPython.Application.instance().kernel.do_shutdown(True)
```

After you get `{'status': 'ok', 'restart': True}`, reinstantiate your environment with the required libraries and just the `BertTokenizer` from Transformers. You will not re-compile the model as you have the `bert-base-uncased-neuron.pt` TorchScript graph available. Also, redefine the `inference_latency()` method.

[ ]:
```
import torch
import torch_neuron
from transformers import BertTokenizer

from joblib import Parallel, delayed
import numpy as np
from tqdm import tqdm

import os
import time

def inference_latency(model,*inputs):
    """
    infetence_time is a simple method to return the latency of a model inference.

        Parameters:
            model: torch model onbject loaded using torch.jit.load
            inputs: model() args

        Returns:
            latency in seconds
    """
    start = time.time()
    _ = model(*inputs)
    return time.time() - start

tokenizer = BertTokenizer.from_pretrained('bert-base-uncased')

inputs = tokenizer("Hello, my dog is cute",return_tensors="pt",max_length=128,padding=
↪'max_length',truncation=True)
```

You use the `'NEURON_RT_NUM_CORES'` environment variable to define how many Neuron cores to be used. Set the environment variable to the number of individual workers you want to test in parallel.

`torch_neuron` will load one model per NeuronCore group until it runs out of cores. At that point, if the Python process continues to spawn more model objest using `torch.jit.load`, `torch_neuron` will start stacking more than one model per core, until the Inferentia chip memory is full.

Inferentia is able to run inference over all the loaded models, but only one at a time. The Neuron Runtime takes care

of dynamically switching the model context as requests come in, no extra worker process management required. Use 1 model per NeuronCore to achieve maximum performance.

The following cell creates a list with as many models as NeuronCore Groups and execute one single dummy inference to load the models into Inferentia.

[ ]:
```
import warnings
# Number of data parallel workers
number_of_workers=16 # This number should be 4 on an inf1.xlarge

# Setting up a data parallel group
os.environ['NEURON_RT_NUM_CORES'] = str(number_of_workers)

# Loading 'number_of_workers' amount of models in Python memory
model_list = [torch.jit.load('bert-base-uncased-neuron.pt') for _ in range(number_of_
↪workers)]

# Dummy inference to load models to Inferentia
_ = [mod(*(inputs['input_ids'],inputs['attention_mask'])) for mod in model_list]
```

Adapt the call to `joblib.Parallel()` iterating over a concatenated version of the `model_list`, to run 'round-robin' calls to each of the model workers.

[ ]:
```
t = tqdm(model_list*1500,position=0, leave=True)
latency = Parallel(n_jobs=number_of_workers,prefer="threads")(delayed(inference_
↪latency)(mod,*(inputs['input_ids'],inputs['attention_mask'])) for mod in t)

p50 = np.quantile(latency[-10000:],0.50) * 1000
p95 = np.quantile(latency[-10000:],0.95) * 1000
p99 = np.quantile(latency[-10000:],0.99) * 1000
avg_throughput = t.total/t.format_dict['elapsed']
print(f'Avg Throughput: :{avg_throughput:.1f}')
print(f'50th Percentile Latency:{p50:.1f} ms')
print(f'95th Percentile Latency:{p95:.1f} ms')
print(f'99th Percentile Latency:{p99:.1f} ms')
```

For this model, despite the larger number of workers, the per-worker latency increases when running a single model per core, which in turn reduces the total throughput.

This behavior may not repeat if the model memory footprint or the input payload size changes, i.e batch size > 1. We encourage you to experiment with the data parallel and pipeline parallel modes to optimize your application performance.

Note: To use Jupyter Notebook see:

- setup-jupyter-notebook-steps-troubleshooting
- running-jupyter-notebook-as-script

- AWS Neuron Samples GitHub Repository

API Reference Guide (torch-neuron)

This document is relevant for: Inf1

8.27 PyTorch-Neuron trace python API

The PyTorch-Neuron trace Python API provides a method to generate PyTorch models for execution on Inferentia, which can be serialized as TorchScript. It is analogous to `torch.jit.trace()` function in PyTorch.

`torch_neuron.trace`(*model*, *example_inputs*, ***kwargs*)

The *`torch_neuron.trace()`* method sends operations to the Neuron-Compiler (`neuron-cc`) for compilation and embeds compiled artifacts in a TorchScript graph.

Compilation can be done on any EC2 machine with sufficient memory and compute resources. c5.4xlarge or larger is recommended.

Options can be passed to Neuron compiler via the compile function. See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.

This function partitions nodes into operations that are supported by Neuron and operations which are not. Operations which are not supported by Neuron are run on CPU. Graph partitioning can be controlled by the `subgraph_builder_function`, `minimum_segment_size`, and `fallback` parameters (See below). By default all supported operations are compiled and run on Neuron.

The compiled graph can be saved using the `torch.jit.save()` function and restored using `torch.jit.load()` function for inference on Inf1 instances. During inference, the previously compiled artifacts will be loaded into the Neuron Runtime for inference execution.

Required Arguments

Parameters

- **`model`** (*`Module,callable`*) – The functions that that will be run with `example_inputs` arguments. The arguments and return types must compatible with `torch.jit.trace()`. When a `Module` is passed to *`torch_neuron.trace()`*, only the `forward()` method is run and traced.
- **`example_inputs`** (*`tuple`*) – A tuple of example inputs that will be passed to the `model` while tracing. The resulting trace can be run with inputs of different types and shapes assuming the traced operations support those types and shapes. This parameter may also be a single `torch.Tensor` in which case it is automatically wrapped in a `tuple`.

Optional Keyword Arguments

Keyword Arguments

- **`compiler_args`** (*`list[str]`*) – List of strings representing `neuron-cc` compiler arguments. Note that these arguments apply to all subgraphs generated by allowlist partitioning. For example, use `compiler_args=['--neuroncore-pipeline-cores', '4']` to set number of NeuronCores per subgraph to 4. See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.
- **`compiler_timeout`** (*`int`*) – Timeout in seconds for waiting `neuron-cc` to complete. Exceeding this timeout will cause a `subprocess.TimeoutExpired` exception.

- **compiler_workdir** (*str*) – Work directory used by `neuron-cc`. Useful for debugging and/or inspecting `neuron-cc` logs/IRs.
- **subgraph_builder_function** (*callable*) – A function which is evaluated on each node during graph partitioning. This takes in a torch graph operator node and returns a `bool` value of whether it should be included in the fused Neuron graph or not. By default the partitioner selects all operators which are supported by Neuron.
- **minimum_segment_size** (*int*) – A parameter used during partitioning. This specifies the minimum number of graph nodes which should be compiled into a Neuron graph (default= `2`). If the number of nodes is smaller than this size, the operations will run on CPU.
- **single_fusion_ratio_threshold** (*float*) – A parameter used during partitioning. During partitioning, if a single partition contains a fraction of operations greater than this threshold, only one graph partition will be compiled (default= `0.6`). This is used to avoid compiling many small Neuron graphs. To force compilation of all graphs to Neuron (even when they are very small), a value of `1.0` can be used.
- **fallback** (*bool*) – A function parameter to turn off graph partitioning. Indicates whether to attempt to fall back to CPU operations if an operation is not supported by Neuron. By default this is `True`. If this is set to `False` and an operation is not supported by Neuron, this will fail compilation and raise an `AttributeError`.
- **dynamic_batch_size** (*bool*) – A flag to allow Neuron graphs to consume variable sized batches of data. Dynamic sizing is restricted to the 0th dimension of a tensor.
- **optimizations** (*list*) – A list of *Optimization* passes to apply to the model.
- ****kwargs** – All other keyword arguments will be forwarded directly to `torch.jit.trace()`. This supports flags like `strict=False` in order to allow dictionary outputs.

Returns

The traced `ScriptModule` with embedded compiled neuron sub-graphs. Operations in this module will run on Neuron unless they are not supported by Neuron or manually partitioned to run on CPU.

Note that in `torch<1.8` This would return a `ScriptFunction` if the input was function type.

Return type *ScriptModule*, *ScriptFunction*

class torch_neuron.**Optimization**

A set of optimization passes that can be applied to the model.

FLOAT32_TO_FLOAT16

A post-processing pass that converts all `torch.float32` tensors to `torch.float16` tensors. The advantage to this optimization pass is that input/output tensors will be type cast. This reduces the amount of data that will be copied to and from Inferentia hardware. The resulting traced model will accept both `torch.float32` and `torch.float16` inputs where the model used `torch.float32` inputs during tracing. It is only beneficial to enable this optimization if the throughput of a model is highly dependent upon data transfer speed. This optimization is not recommended if the final application will use `torch.float32` inputs since the `torch.float16` type cast will occur on CPU during inference.

8.27.1 Example Usage

Function Compilation

```
import torch
import torch_neuron

def foo(x, y):
    return 2 * x + y

# Run `foo` with the provided inputs and record the tensor operations
traced_foo = torch.neuron.trace(foo, (torch.rand(3), torch.rand(3)))

# `traced_foo` can now be run with the TorchScript interpreter or saved
# and loaded in a Python-free environment
torch.jit.save(traced_foo, 'foo.pt')
traced_foo = torch.jit.load('foo.pt')
```

Module Compilation

```
import torch
import torch_neuron
import torch.nn as nn

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv = nn.Conv2d(1, 1, 3)

    def forward(self, x):
        return self.conv(x) + 1

n = Net()
n.eval()

inputs = torch.rand(1, 1, 3, 3)

# Trace a specific method and construct `ScriptModule` with
# a single `forward` method
neuron_forward = torch.neuron.trace(n.forward, inputs)

# Trace a module (implicitly traces `forward`) and constructs a
# `ScriptModule` with a single `forward` method
neuron_net = torch.neuron.trace(n, inputs)
```

Pre-Trained Model Compilation

The following is an example usage of the compilation Python API, with default compilation arguments, using a pre-trained `torch.nn.Module`:

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)
```

Compiling models with torch.jit.trace kwargs

This example uses the `strict=False` flag to compile a model with dictionary outputs. Similarly, any other keyword argument of `torch.jit.trace()` can be passed directly to *`torch_neuron.trace()`* so that it is passed to the underlying trace call.

```
import torch
import torch_neuron
import torch.nn as nn

class Model(nn.Module):
    def __init__(self):
        super(Model, self).__init__()
        self.conv = nn.Conv2d(1, 1, 3)

    def forward(self, x):
        return {'conv': self.conv(x) + 1}

model = Model()
model.eval()

inputs = torch.rand(1, 1, 3, 3)

# use the strict=False kwarg to compile a model with dictionary outputs
# the model output format does not change
model_neuron = torch.neuron.trace(model, inputs, strict=False)
```

Dynamic Batching

This example uses the optional `dynamic_batch_size` option in order to support variable sized batches at inference time.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input of batch size 1
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image, dynamic_batch_size=True)

# Execute with a batch of 7 images
batch = torch.rand([7, 3, 224, 224])
results = model_neuron(batch)
```

Manual Partitioning

The following example uses the optional `subgraph_builder_function` parameter to ensure that only a specific convolution layer is compiled to Neuron. The remaining operations are executed on CPU.

```
import torch
import torch_neuron
import torch.nn as nn

class ExampleConvolutionLayer(nn.Module):
    def __init__(self):
        super().__init__()
        self.conv = nn.Conv2d(1, 1, 3)

    def forward(self, x):
        return self.conv(x) + 1

class Model(nn.Module):
    def __init__(self):
        super().__init__()
        self.layer = ExampleConvolutionLayer()

    def forward(self, x):
        return self.layer(x) * 100

def subgraph_builder_function(node) -> bool:
    """Select if the node will be included in the Neuron graph"""

    # Node names are tuples of Module names.
    if 'ExampleConvolutionLayer' in node.name:
        return True
```

(continues on next page)

(continued from previous page)

```
    # Ignore all operations not in the example convolution layer
    return False

model = Model()
model.eval()

inputs = torch.rand(1, 1, 3, 3)

# Log output shows that `aten::_convolution` and `aten::add` are compiled
# but `aten::mul` is not. This will seamlessly switch between Neuron/CPU
# execution in a single graph.
neuron_model = torch_neuron.trace(
    model,
    inputs,
    subgraph_builder_function=subgraph_builder_function
)
```

8.28 torch.neuron.DataParallel API

The *torch.neuron.DataParallel()* Python API implements data parallelism on ScriptModule models created by the /neuron-guide/neuron-frameworks/pytorch-neuron/api-compilation-python-api.rst. This function is analogous to DataParallel in PyTorch. The *Data Parallel Inference on Torch Neuron* application note provides an overview of how *torch.neuron.DataParallel()* can be used to improve the performance of inference workloads on Inferentia.

torch.neuron.**DataParallel**(*model*, *device_ids=None*, *dim=0*)

Applies data parallelism by replicating the model on available NeuronCores and distributing data across the different NeuronCores for parallelized inference.

By default, DataParallel will use all available NeuronCores allocated for the current process for parallelism. DataParallel will apply parallelism on `dim=0` if `dim` is not specified.

DataParallel automatically enables *dynamic batching* on eligible models if `dim=0`. Dynamic batching can be dsiabled using *torch.neuron.DataParallel.disable_dynamic_batching()*. If dynamic batching is not enabled, the batch size at compilation-time must be equal to the batch size at inference-time divided by the number of NeuronCores being used. Specifically, the following must be true when dynamic batching is disabled: `input.shape[dim] / len(device_ids) == compilation_input.shape[dim]`. DataParallel will throw a warning if dynamic batching cannot be enabled.

DataParallel will try load all of a model's NEFFs onto a single NeuronCore, only if all of the NEFFs can fit on a single NeuronCore. DataParallel does not currently support models that have been compiled with *NeuronCore Pipeline*.

torch.neuron.DataParallel() requires PyTorch >= 1.8.

Required Arguments

Parameters **model** (*ScriptModule*) – Model created by the /neuron-guide/neuron-frameworks/pytorch-neuron/api-compilation-python-api.rst to be parallelized.

Optional Arguments

Parameters

- **device_ids** (*list*) – List of `int` or `'nc:#'` that specify the NeuronCores to use for parallelization (default: all NeuronCores). Refer to the *device_ids note* for a description of how `device_ids` indexing works.
- **dim** (*int*) – Dimension along which the input tensor is scattered across NeuronCores (default `dim=0`).

Attributes

Parameters

- **num_workers** (*int*) – Number of worker threads used for multithreaded inference (default: `2 * number of NeuronCores`).
- **split_size** (*int*) – Size of the input chunks (default: `max(1, input.shape[dim] // number of NeuronCores)`).

`torch.neuron.DataParallel.`**`disable_dynamic_batching`**`()`

Disables automatic dynamic batching on the DataParallel module. See *Dynamic batching disabled* for example of how DataParallel can be used with dynamic batching disabled. Use as follows:

```
>>> model_parallel = torch.neuron.DataParallel(model_neuron)
>>> model_parallel.disable_dynamic_batching()
```

Note: `device_ids` uses per-process NeuronCore granularity and zero-based indexing. Per-process granularity means that each Python process "sees" its own view of the world. Specifically, this means that `device_ids` only "sees" the NeuronCores that are allocated for the current process. Zero-based indexing means that each Python process will index its allocated NeuronCores starting at 0, regardless of the "global" index of the NeuronCores. Zero-based indexing makes it possible to redeploy the exact same code unchanged in different process. This behavior is analogous to the `device_ids` argument in the PyTorch `DataParallel` function.

As an example, assume DataParallel is run on an inf1.6xlarge, which contains four Inferentia chips each of which contains four NeuronCores:

- If `NEURON_RT_VISIBLE_CORES` is not set, a single process can access all 16 NeuronCores. Thus specifying `device_ids=["nc:0"]` will correspond to chip0:core0 and `device_ids=["nc:14"]` will correspond to chip3:core2.
- However, if two processes are launched where: process 1 has `NEURON_RT_VISIBLE_CORES=0-6` and process 2 has `NEURON_RT_VISIBLE_CORES=7-15`, `device_ids=["nc:14"]` cannot be specified in either process. Instead, chip3:core2 can only be accessed in process 2. Additionally, chip3:core2 is specified in process 2 with `device_ids=["nc:7"]`. Furthermore, in process 1, `device_ids=["nc:0"]` would correspond to chip0:core0; in process 2 `device_ids=["nc:0"]` would correspond to chip1:core3.

8.28.1 Examples

The following sections provide example usages of the *torch.neuron.DataParallel()* module.

Default usage

The default DataParallel use mode will replicate the model on all available NeuronCores in the current process. The inputs will be split on `dim=0`.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module
model_parallel = torch.neuron.DataParallel(model_neuron)

# Create a batched input
batch_size = 5
image_batched = torch.rand([batch_size, 3, 224, 224])

# Run inference with a batched input
output = model_parallel(image_batched)
```

Specifying NeuronCores

The following example uses the `device_ids` argument to use the first three NeuronCores for DataParallel inference.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module, run on the first three NeuronCores
# Equivalent to model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=[0,␣
↪1, 2])
model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=['nc:0', 'nc:1', 'nc:
↪2'])
```

(continues on next page)

(continued from previous page)

```
# Create a batched input
batch_size = 5
image_batched = torch.rand([batch_size, 3, 224, 224])

# Run inference with a batched input
output = model_parallel(image_batched)
```

DataParallel with dim != 0

In this example we run DataParallel inference using four NeuronCores and `dim = 2`. Because `dim != 0`, dynamic batching is not enabled. Consequently, the DataParallel inference-time batch size must be four times the compile-time batch size. DataParallel will generate a warning that dynamic batching is disabled because `dim != 0`.

```
import torch
import torch_neuron

# Create an example model
class Model(torch.nn.Module):
    def __init__(self):
        super().__init__()
        self.conv = torch.nn.Conv2d(3, 3, 3)

    def forward(self, x):
        return self.conv(x) + 1

model = Model()
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 8, 8])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module using 4 NeuronCores and dim = 2
model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=[0, 1, 2, 3], dim=2)

# Create a batched input
# Note that image_batched.shape[dim] / len(device_ids) == image.shape[dim]
batch_size = 4 * 8
image_batched = torch.rand([1, 3, batch_size, 8])

# Run inference with a batched input
output = model_parallel(image_batched)
```

Dynamic batching

In the following example, we use the *torch.neuron.DataParallel()* module to run inference using several different batch sizes without recompiling the Neuron model.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module
model_parallel = torch.neuron.DataParallel(model_neuron)

# Create batched inputs and run inference on the same model
batch_sizes = [2, 3, 4, 5, 6]
for batch_size in batch_sizes:
    image_batched = torch.rand([batch_size, 3, 224, 224])

    # Run inference with a batched input
    output = model_parallel(image_batched)
```

Dynamic batching disabled

In the following example, we use *torch.neuron.DataParallel.disable_dynamic_batching()* to disable dynamic batching. We provide an example of a batch size that will not work when dynamic batching is disabled as well as an example of a batch size that does work when dynamic batching is disabled.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module and use 4 NeuronCores
model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=[0, 1, 2, 3], dim=0)

# Disable dynamic batching
model_parallel.disable_dynamic_batching()
```

(continues on next page)

(continued from previous page)

```
# Create a batched input (this won't work)
batch_size = 8
image_batched = torch.rand([batch_size, 3, 224, 224])

# This will fail because dynamic batching is disabled and
# image_batched.shape[dim] / len(device_ids) != image.shape[dim]
# output = model_parallel(image_batched)

# Create a batched input (this will work)
batch_size = 4
image_batched = torch.rand([batch_size, 3, 224, 224])

# This will work because
# image_batched.shape[dim] / len(device_ids) == image.shape[dim]
output = model_parallel(image_batched)
```

8.29 Experimental: NeuronCore Placement APIs

Warning: The following functionality is experimental and **will not be supported** in future releases of the NeuronSDK. This module serves only as a preview for future functionality. In future releases, equivalent functionality may be moved directly to the `torch_neuron` module and will no longer be available in the `torch_neuron.experimental` module.

Functions which enable placement of `torch.jit.ScriptModule` to specific NeuronCores. Two sets of functions are provided which can be used interchangeably but have different performance characteristics and advantages:

- The *`multicore_context()`* & *`neuron_cores_context()`* functions are context managers that allow a model to be placed on a given NeuronCore at `torch.jit.load()` time. These functions are the most efficient way of loading a model since the model is loaded directly to a NeuronCore. The alternative functions described below require that a model is unloaded from one core and then reloaded to another.
- The *`set_multicore()`* & *`set_neuron_cores()`* functions allow a model that has already been loaded to a NeuronCore to be moved to a different NeuronCore. This functionality is less efficient than directly loading a model to a NeuronCore within a context manager but allows device placement to be fully dynamic at runtime. This is analogous to the `torch.nn.Module.to()` function for device placement.

Important: A prerequisite to enable placement functionality is that the loaded `torch.jit.ScriptModule` has already been compiled with the *`torch_neuron.trace()`* API. Attempting to place a regular `torch.nn.Module` onto a NeuronCore prior to compilation will do nothing.

`torch_neuron.experimental.multicore_context()`

A context which loads all Neuron subgraphs to all visible NeuronCores.

This loads each Neuron subgraph within a `torch.jit.ScriptModule` to multiple NeuronCores without requiring multiple calls to `torch.jit.load()`. This allows a single `torch.jit.ScriptModule` to use multiple NeuronCores for concurrent threadsafe inferences. Executions use a round-robin strategy to distribute across NeuronCores.

Any calls to `torch.jit.load()` will cause any underlying Neuron subgraphs to load to the specified NeuronCores within this context. This context manager only needs to be used during the model load. After loading, inferences do not need to occur in this context in order to use the correct NeuronCores.

Note that this context is *not* threadsafe. Using multiple core placement contexts from multiple threads may not correctly place models.

Raises `RuntimeError` – If the Neuron runtime cannot be initialized.

Examples

Multiple Core Replication: Directly load a model to all visible NeuronCores. This allows a single `torch.jit.ScriptModule` to use all NeuronCores by running round-robin executions.

```
>>> with torch_neuron.experimental.multicore_context():
>>>     model = torch.jit.load('example_neuron_model.pt')
>>> model(example) # Executes on NeuronCore 0
>>> model(example) # Executes on NeuronCore 1
>>> model(example) # Executes on NeuronCore 2
```

`torch_neuron.experimental.neuron_cores_context(start_nc: int = - 1, nc_count: int = - 1)`

A context which sets the NeuronCore start/count for all Neuron subgraphs.

Any calls to `torch.jit.load()` will cause any underlying Neuron subgraphs to load to the specified NeuronCores within this context. This context manager only needs to be used during the model load. After loading, inferences do not need to occur in this context in order to use the correct NeuronCores.

Note that this context is *not* threadsafe. Using multiple core placement contexts from multiple threads may not correctly place models.

Parameters

- **start_nc** – The starting NeuronCore index where the Module is placed. The value `-1` automatically loads to the optimal NeuronCore (least used). Note that this index is always relative to NeuronCores visible to this process.
- **nc_count** – The number of NeuronCores to use. The value `-1` will load a model to exactly the number of cores required by that model (1 for most models, >1 when using NeuronCore Pipeline). If `nc_count` is greater than the number of NeuronCores required by the model, the model will be replicated across multiple NeuronCores. `(replications = floor(nc_count / cores_per_model))`

Raises

- `RuntimeError` – If the Neuron runtime cannot be initialized.
- `ValueError` – If the `nc_count` is an invalid number of NeuronCores.

Examples

Single Load: Directly load a model from disk to the first visible NeuronCore.

```
>>> with torch_neuron.experimental.neuron_cores_context(start_nc=0, nc_count=1):
>>>     model = torch.jit.load('example_neuron_model.pt')
>>> model(example) # Executes on NeuronCore 0
>>> model(example) # Executes on NeuronCore 0
>>> model(example) # Executes on NeuronCore 0
```

Multiple Core Replication: Directly load a model from disk to 2 NeuronCores. This allows a single `torch.jit.ScriptModule` to use multiple NeuronCores by running round-robin executions.

```
>>> with torch_neuron.experimental.neuron_cores_context(start_nc=2, nc_count=2):
>>>     model = torch.jit.load('example_neuron_model.pt')
>>> model(example) # Executes on NeuronCore 2
>>> model(example) # Executes on NeuronCore 3
>>> model(example) # Executes on NeuronCore 2
```

Multiple Model Load: Directly load 2 models from disk and pin them to separate NeuronCores. This causes each `torch.jit.ScriptModule` to always execute on a specific NeuronCore.

```
>>> with torch_neuron.experimental.neuron_cores_context(start_nc=2):
>>>     model1 = torch.jit.load('example_neuron_model.pt')
>>> with torch_neuron.experimental.neuron_cores_context(start_nc=0):
>>>     model2 = torch.jit.load('example_neuron_model.pt')
>>> model1(example) # Executes on NeuronCore 2
>>> model1(example) # Executes on NeuronCore 2
>>> model2(example) # Executes on NeuronCore 0
>>> model2(example) # Executes on NeuronCore 0
```

`torch_neuron.experimental.`**`set_multicore`**(*trace: torch.jit.ScriptModule*)

Loads all Neuron subgraphs in a torch Module to all visible NeuronCores.

This loads each Neuron subgraph within a `torch.jit.ScriptModule` to multiple NeuronCores without requiring multiple calls to `torch.jit.load()`. This allows a single `torch.jit.ScriptModule` to use multiple NeuronCores for concurrent threadsafe inferences. Executions use a round-robin strategy to distribute across NeuronCores.

This will unload the model from an existing NeuronCore if it is already loaded.

Requires Torch 1.8+

Parameters **`trace`** – A torch module which contains one or more Neuron subgraphs.

Raises `RuntimeError` – If the Neuron runtime cannot be initialized.

Examples

Multiple Core Replication: Move a model across all visible NeuronCores after loading. This allows a single `torch.jit.ScriptModule` to use all NeuronCores by running round-robin executions.

```
>>> model = torch.jit.load('example_neuron_model.pt')
>>> torch_neuron.experimental.set_multicore(model)
>>> model(example) # Executes on NeuronCore 0
>>> model(example) # Executes on NeuronCore 1
>>> model(example) # Executes on NeuronCore 2
```

`torch_neuron.experimental.`**`set_neuron_cores`**(*trace: torch.jit.ScriptModule*, *start_nc: int = - 1*, *nc_count: int = - 1*)

Set the NeuronCore start/count for all Neuron subgraphs in a torch Module.

This will unload the model from an existing NeuronCore if it is already loaded.

Requires Torch 1.8+

Parameters

- **`trace`** – A torch module which contains one or more Neuron subgraphs.
- **`start_nc`** – The starting NeuronCore index where the Module is placed. The value `-1` automatically loads to the optimal NeuronCore (least used). Note that this index is always relative to NeuronCores visible to this process.
- **`nc_count`** – The number of NeuronCores to use. The value `-1` will load a model to exactly the number of cores required by that model (1 for most models, >1 when using NeuronCore Pipeline). If `nc_count` is greater than the number of NeuronCores required by the model, the model will be replicated across multiple NeuronCores. `(replications = floor(nc_count / cores_per_model))`

Raises

- **`RuntimeError`** – If the Neuron runtime cannot be initialized.
- **`ValueError`** – If the `nc_count` is an invalid number of NeuronCores.

Examples

Single Load: Move a model to the first visible NeuronCore after loading.

```
>>> model = torch.jit.load('example_neuron_model.pt')
>>> torch_neuron.experimental.set_neuron_cores(model, start_nc=0, nc_count=1)
>>> model(example) # Executes on NeuronCore 0
>>> model(example) # Executes on NeuronCore 0
>>> model(example) # Executes on NeuronCore 0
```

Multiple Core Replication: Replicate a model to 2 NeuronCores after loading. This allows a single `torch.jit.ScriptModule` to use multiple NeuronCores by running round-robin executions.

```
>>> model = torch.jit.load('example_neuron_model.pt')
>>> torch_neuron.experimental.set_neuron_cores(model, start_nc=2, nc_count=2)
>>> model(example) # Executes on NeuronCore 2
>>> model(example) # Executes on NeuronCore 3
>>> model(example) # Executes on NeuronCore 2
```

Multiple Model Load: Move and pin 2 models to separate NeuronCores. This causes each `torch.jit.ScriptModule` to always execute on a specific NeuronCore.

```
>>> model1 = torch.jit.load('example_neuron_model.pt')
>>> torch_neuron.experimental.set_neuron_cores(model1, start_nc=2)
>>> model2 = torch.jit.load('example_neuron_model.pt')
>>> torch_neuron.experimental.set_neuron_cores(model2, start_nc=0)
>>> model1(example) # Executes on NeuronCore 2
>>> model1(example) # Executes on NeuronCore 2
>>> model2(example) # Executes on NeuronCore 0
>>> model2(example) # Executes on NeuronCore 0
```

  - *End-to-end natural language processing bucketing example*

8.30.1 Introduction

With Inferentia, the shape of every input must be fixed at compile time. For applications that require multiple input sizes, we recommend using padding or bucketing techniques. Padding requires you to compile your model with the largest expected input size and pad every input to this maximum size. If the performance of your model using padding is not within your targets, you can consider implementing bucketing.

This guide introduces bucketing, a technique to run inference on inputs with variable shapes on Inferentia. The following sections explain how bucketing can improve the performance of inference workloads on Inferentia. It covers an overview of how bucketing works and provides examples of using bucketing in *computer vision* and *natural language processing* applications.

8.30.2 Applications that benefit from bucketing

Bucketing refers to compiling your model multiple times with different target input shapes to create "bucketed models." *Creating bucketed models* provides an overview on selecting the input shapes that you use to create bucketed models. At inference time, each input is padded until its shape matches the next largest bucket shape. The padded input is then passed into the corresponding bucketed model for inference. By compiling the same model with multiple different input shapes, the amount of input padding is reduced compared to padding every input to the maximum size in your dataset. This technique minimizes the compute overhead and improves inference performance compared to padding every image to the maximum shape in your dataset.

Bucketing works best when multiple different bucketed models are created to efficiently cover the full range of input shapes. You can fine-tune the model performance by experimenting with different bucket sizes that correspond to the distribution of input shapes in your dataset.

Bucketing can only be used if there is an upper bound on the shape of the inputs. If necessary, an upper bound on the input shape can be enforced using resizing and other forms of preprocessing.

The upper bound on the number of bucketed models that you use is dictated by the total size of the compiled bucketed models. Each Inferentia chip has 8GB of DRAM, or 2GB of DRAM per NeuronCore. An inf1.xlarge and inf1.2xlarge have 1 Inferentia chip, an inf1.6xlarge has 4 Inferentia chips, and an inf1.24xlarge has 16 Inferentia chips. Thus, you should limit the total size of all bucketed models to around 8GB per Inferentia chip or 2GB per NeuronCore. The following formula provides an approximation for the number of compiled bucketed models you can fit on each NeuronCore:

```
number-of-buckets = round(10^9 / number-of-weights-in-model)
```

We recommend using *neuron-top* to monitor the memory usage on your inf1 instance as you load multiple bucketed models.

8.30.3 Implementing bucketing

Implementing bucketing consists of two main parts: creating multiple bucketed models at compile-time and running inference using the bucketed models on (padded) inputs. The following sections describe how to implement bucketing to run inference in applications that have variable input shapes.

Creating bucketed models

Before running inference, models should be compiled for different input shapes that are representative of the input dataset. The input shapes that are used to compile the models determine the bucket shapes that are used during inference. The bucket shapes should be chosen to minimize the amount of padding on each new input. Additionally, there should always be a bucket that's large enough to handle the maximum input shape in the dataset. The limit on the number of compiled bucketed models that can be used is described in this *section*.

Running inference with bucketing

At inference time, each input should be padded to match the size of the next largest bucket, such that the height and width (or sequence length) of the padded input equals the size of the bucket. Then, the padded input should be passed into the corresponding bucket for inference. If necessary, it's important to remove and/or crop any aberrant predictions that occur in the padded region. For example, in object detection applications, bounding box predictions that occur in the padded regions should be removed to avoid erroneous predictions.

8.30.4 Examples

The following sections provide examples of applying the bucketing technique to run inference in applications that have variable input shapes.

Computer vision bucketing

As an example of implementing bucketing for computer vision models, consider an application where the height and width of images in dataset are uniformly distributed between *[400, 400]* and *[800, 800]*. Given that every input shape between *[400, 400]* and *[800, 800]* is equally likely, it could make sense to create bucketed models that divide up the range of input shapes into equally sized chunks. For example, we could create bucketed models for the input shapes *[500, 500]*, *[600, 600]*, *[700, 700]*, and *[800, 800]*.

As an example of running inference with bucketing, let's assume that we created bucketed models for the input shapes *[500, 500]*, *[600, 600]*, *[700, 700]*, and *[800, 800]*. If we receive an input with shape *[640, 640]*, we would pad the input to the next largest bucket, *[700, 700]*, and use this bucket for inference. If we receive an input with shape *[440, 540]*, we would need to pad the input to the bucket size, *[600, 600]*, and use this bucket for inference.

As another example of creating bucketed models, consider a computer vision application where the dataset is not uniformly distributed. As before, let's assume the input shapes range between *[400, 400]* to *[800, 800]*. Now, let's assume the data shape distribution is bimodal, such that *[540, 540]* and *[720, 720]* are the two most common input shapes. In this example, it might make sense to create bucketed models for input shapes *[540, 540]*, *[720, 720]*, and *[800, 800]* to target the most common shapes while still including the entire range of input shapes.

End-to-end computer vision bucketing example

In this example, we run inference in a computer vision application that has variable shaped images that range in shape from *[400, 400]* to *[800, 800]*. We create bucketed models for the input shapes *[500, 500]*, *[600, 600]*, *[700, 700]*, and *[800, 800]* to handle the variable input shapes.

```
import numpy as np
import torch
from torchvision import models
import torch_neuron

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Define the bucket sizes that will be used for compilation and inference
bucket_sizes = [(500, 500), (600, 600), (700, 700), (800, 800)]

# Create the bucketed models by compiling a model for each bucket size
buckets = {}
for bucket_size in bucket_sizes:
    # Create an example input that is the desired bucket size
    h, w = bucket_size
    image = torch.rand([1, 3, h, w])

    # Compile with the example input to create the bucketed model
    model_neuron = torch.neuron.trace(model, image)

    # Run a warm up inference to load the model into Inferentia memory
```

(continues on next page)

(continued from previous page)

```
    model_neuron(image)

    # Add the bucketed model based on its bucket size
    buckets[bucket_size] = model_neuron

def get_bucket_and_pad_image(image):
    # Determine which bucket size to use
    oh, ow = image.shape[-2:]
    target_bucket = None
    for bucket_size in bucket_sizes:
        # Choose a bucket that's larger in both the height and width dimensions
        if oh <= bucket_size[0] and ow <= bucket_size[1]:
            target_bucket = bucket_size
            break

    # Pad the image to match the size of the bucket
    h_delta = target_bucket[0] - oh
    w_delta = target_bucket[1] - ow

    b_pad = h_delta  # Bottom padding
    l_pad = 0  # Left padding
    t_pad = 0  # Top padding
    r_pad = w_delta  # Right padding

    # Pad the height and width of the image
    padding_amounts = (l_pad, r_pad, t_pad, b_pad)
    image_padded = torch.nn.functional.pad(image, padding_amounts, value=0)

    return image_padded, target_bucket

# Run inference on inputs with different shapes
for _ in range(10):
    # Create an image with a random height and width in range [400, 400] to [800, 800]

    w = int(np.random.uniform(low=400, high=800))
    image = torch.rand(1, 3, h, w)

    # Determine bucket and pad the image
    image_padded, target_bucket = get_bucket_and_pad_image(image)

    # Use the corresponding bucket to run inference
    output = buckets[target_bucket](image_padded)
```

Natural language processing bucketing

As an example of implementing bucketing for natural language processing models, consider an application where the lengths of tokenized sequences in a dataset are uniformly distributed between 0 and 128 tokens. Given that every tokenized sequence length between 0 and 128 is equally likely, it might make sense to create bucketed models that divide up the range of tokenized sequence lengths into equally sized chunks. For example, we could create bucketed models for tokenized sequence lengths 64 and 128.

As an example of running inference with bucketing, let's assume that we created bucketed models for the input tokenized sequence lengths 64 and 128. If we receive a tokenized sequence with length 55, we would need to pad it to the bucket size 64 and use this bucket for inference. If we receive a tokenized sequence with length 112, we would need to pad it to the bucket size 128 and use this bucket for inference.

End-to-end natural language processing bucketing example

In this example, we run inference in a natural language processing application that has variable length tokenized sequences that range from 0 to 128. We create bucketed models for lengths 64 and 128 to handle the variable input lengths.

```
import numpy as np
import torch
from transformers import AutoTokenizer, AutoModelForSequenceClassification
import torch_neuron

# Build tokenizer and model
tokenizer = AutoTokenizer.from_pretrained("bert-base-cased-finetuned-mrpc")
model = AutoModelForSequenceClassification.from_pretrained("bert-base-cased-finetuned-
↪mrpc", return_dict=False)
model.eval()

# Define the bucket sizes that will be used for compilation and inference
bucket_sizes = [64, 128]

# Create the bucketed models by compiling a model for each bucket size
buckets = {}
for bucket_size in bucket_sizes:
    # Setup some example inputs
    sequence_0 = "The company HuggingFace is based in New York City"
    sequence_1 = "HuggingFace's headquarters are situated in Manhattan"

    # Create an example input that is the desired bucket size
    paraphrase = tokenizer.encode_plus(sequence_0,
                                       sequence_1,
                                       max_length=bucket_size,
                                       padding='max_length',
                                       truncation=True,
                                       return_tensors="pt")

    # Convert example inputs to a format that is compatible with TorchScript tracing
    example_inputs_paraphrase = paraphrase['input_ids'], paraphrase['attention_mask'],␣
↪paraphrase['token_type_ids']

    # Compile with the example input to create the bucketed model
```

(continues on next page)

(continued from previous page)

```
    model_neuron = torch.neuron.trace(model, example_inputs_paraphrase)

    # Run a warm up inference to load the model into Inferentia memory
    model_neuron(*example_inputs_paraphrase)

    # Add the bucketed model based on its bucket size
    buckets[bucket_size] = model_neuron

def get_bucket_and_pad_paraphrase(paraphrase):
    # Determine which bucket size to use

8.31.1 Introduction

This guide introduces `torch.neuron.DataParallel()`, a Python API that implements data parallelism on `ScriptModule` models created by the /neuron-guide/neuron-frameworks/pytorch-neuron/api-compilation-python-api.rst. The following sections explain how data parallelism can improve the performance of inference workloads on Inferentia, including how `torch.neuron.DataParallel()` uses dynamic batching to run inference on variable input sizes. It covers an overview of the `torch.neuron.DataParallel()` module and provides a few *example data parallel applications*.

8.31.2 Data parallel inference

Data Parallelism is a form of parallelization across multiple devices or cores, referred to as nodes. Each node contains the same model and parameters, but data is distributed across the different nodes. By distributing the data across multiple nodes, data parallelism reduces the total execution time of large batch size inputs compared to sequential execution. Data parallelism works best for smaller models in latency sensitive applications that have large batch size requirements.

8.31.3 torch.neuron.DataParallel

To fully leverage the Inferentia hardware, we want to use all available NeuronCores. An inf1.xlarge and inf1.2xlarge have four NeuronCores, an inf1.6xlarge has 16 NeuronCores, and an inf1.24xlarge has 64 NeuronCores. For maximum performance on Inferentia hardware, we can use `torch.neuron.DataParallel()` to utilize all available NeuronCores.

`torch.neuron.DataParallel()` implements data parallelism at the module level by replicating the Neuron model on all available NeuronCores and distributing data across the different cores for parallelized inference. This function is analogous to `DataParallel` in PyTorch. `torch.neuron.DataParallel()` requires PyTorch >= 1.8.

The following sections provide an overview of some of the features of `torch.neuron.DataParallel()` that enable maximum performance on Inferentia.

NeuronCore selection

By default, DataParallel will try to use all NeuronCores allocated to the current process to fully saturate the Inferentia hardware for maximum performance. It is more efficient to make the batch dimension divisible by the number of NeuronCores. This will ensure that NeuronCores are not left idle during parallel inference and the Inferentia hardware is fully utilized.

In some applications, it is advantageous to use a subset of the available NeuronCores for DataParallel inference. DataParallel has a `device_ids` argument that accepts a list of `int` or `'nc:#'` that specify the NeuronCores to use for parallelization. See *Specifying NeuronCores* for an example of how to use `device_ids` argument.

Batch dim

DataParallel accepts a `dim` argument that denotes the batch dimension used to split the input data for distributed inference. By default, DataParalell splits the inputs on `dim = 0` if the `dim` argument is not specified. For applications with a non-zero batch dim, the `dim` argument can be used to specify the inference-time input batch dimension. *DataParallel with dim ! = 0* provides an example of data parallel inference on inputs with batch dim = 2.

Dynamic batching

Batch size has a direct impact on model performance. The Inferentia chip is optimized to run with small batch sizes. This means that a Neuron compiled model can outperform a GPU model, even if running single digit batch sizes.

As a general best practice, we recommend optimizing your model's throughput by compiling the model with a small batch size and gradually increasing it to find the peak throughput on Inferentia.

Dynamic batching is a feature that allows you to use tensor batch sizes that the Neuron model was not originally compiled against. This is necessary because the underlying Inferentia hardware will always execute inferences with the batch size used during compilation. Fixed batch size execution allows tuning the input batch size for optimal performance. For example, batch size 1 may be best suited for an ultra-low latency on-demand inference application, while batch size > 1 can be used to maximize throughput for offline inferencing. Dynamic batching is implemented by slicing large input tensors into chunks that match the batch size used during the `torch_neuron.trace()` compilation call.

The `torch.neuron.DataParallel()` class automatically enables dynamic batching on eligible models. This allows us to run inference in applications that have inputs with a variable batch size without needing to recompile the model. See *Dynamic batching* for an example of how DataParallel can be used to run inference on inputs with a dynamic batch size without needing to recompile the model.

Dynamic batching using small batch sizes can result in sub-optimal throughput because it involves slicing tensors into chunks and iteratively sending data to the hardware. Using a larger batch size at compilation time can use the Inferentia hardware more efficiently in order to maximize throughput. You can test the tradeoff between individual request latency and total throughput by fine-tuning the input batch size.

Automatic batching in the DataParallel module can be disabled using the `disable_dynamic_batching()` function as follows:

```
>>> model_parallel = torch.neuron.DataParallel(model_neuron)
>>> model_parallel.disable_dynamic_batching()
```

If dynamic batching is disabled, the compile-time batch size must be equal to the inference-time batch size divided by the number of NeuronCores. *DataParallel with dim != 0* and *Dynamic batching disabled* provide examples of running DataParallel inference with dynamic batching disabled.

Performance optimizations

The DataParallel module has a `num_workers` attribute that can be used to specify the number of worker threads used for multithreaded inference. By default, `num_workers = 2 * number of NeuronCores`. This value can be fine tuned to optimize DataParallel performance.

DataParallel has a `split_size` attribute that dictates the size of the input chunks that are distributed to each NeuronCore. By default, `split_size = max(1, input.shape[dim] // number of NeuronCores)`. This value can be modified to optimally match the inference input chunk size with the compile-time batch size.

8.31.4 Examples

The following sections provide example usages of the *torch.neuron.DataParallel()* module.

Default usage

The default DataParallel use mode will replicate the model on all available NeuronCores in the current process. The inputs will be split on `dim=0`.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module
model_parallel = torch.neuron.DataParallel(model_neuron)

# Create a batched input
batch_size = 5
image_batched = torch.rand([batch_size, 3, 224, 224])

# Run inference with a batched input
output = model_parallel(image_batched)
```

Specifying NeuronCores

The following example uses the `device_ids` argument to use the first three NeuronCores for DataParallel inference.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module, run on the first three NeuronCores
# Equivalent to model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=[0,␣
↪1, 2])
model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=['nc:0', 'nc:1', 'nc:
↪2'])
```

(continues on next page)

(continued from previous page)

```
# Create a batched input
batch_size = 5
image_batched = torch.rand([batch_size, 3, 224, 224])

# Run inference with a batched input
output = model_parallel(image_batched)
```

DataParallel with dim != 0

In this example we run DataParallel inference using four NeuronCores and `dim = 2`. Because `dim != 0`, dynamic batching is not enabled. Consequently, the DataParallel inference-time batch size must be four times the compile-time batch size. DataParallel will generate a warning that dynamic batching is disabled because `dim != 0`.

```
import torch
import torch_neuron

# Create an example model
class Model(torch.nn.Module):
    def __init__(self):
        super().__init__()
        self.conv = torch.nn.Conv2d(3, 3, 3)

    def forward(self, x):
        return self.conv(x) + 1

model = Model()
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 8, 8])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module using 4 NeuronCores and dim = 2
model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=[0, 1, 2, 3], dim=2)

# Create a batched input
# Note that image_batched.shape[dim] / len(device_ids) == image.shape[dim]
batch_size = 4 * 8
image_batched = torch.rand([1, 3, batch_size, 8])

# Run inference with a batched input
output = model_parallel(image_batched)
```

Dynamic batching

In the following example, we use the *torch.neuron.DataParallel()* module to run inference using several different batch sizes without recompiling the Neuron model.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module
model_parallel = torch.neuron.DataParallel(model_neuron)

# Create batched inputs and run inference on the same model
batch_sizes = [2, 3, 4, 5, 6]
for batch_size in batch_sizes:
    image_batched = torch.rand([batch_size, 3, 224, 224])

    # Run inference with a batched input
    output = model_parallel(image_batched)
```

Dynamic batching disabled

In the following example, we use *torch.neuron.DataParallel.disable_dynamic_batching()* to disable dynamic batching. We provide an example of a batch size that will not work when dynamic batching is disabled as well as an example of a batch size that does work when dynamic batching is disabled.

```
import torch
import torch_neuron
from torchvision import models

# Load the model and set it to evaluation mode
model = models.resnet50(pretrained=True)
model.eval()

# Compile with an example input
image = torch.rand([1, 3, 224, 224])
model_neuron = torch.neuron.trace(model, image)

# Create the DataParallel module and use 4 NeuronCores
model_parallel = torch.neuron.DataParallel(model_neuron, device_ids=[0, 1, 2, 3], dim=0)

# Disable dynamic batching
model_parallel.disable_dynamic_batching()
```

(continues on next page)

(continued from previous page)

```
# Create a batched input (this won't work)
batch_size = 8
image_batched = torch.rand([batch_size, 3, 224, 224])

# This will fail because dynamic batching is disabled and
# image_batched.shape[dim] / len(device_ids) != image.shape[dim]
# output = model_parallel(image_batched)

# Create a batched input (this will work)
batch_size = 4
image_batched = torch.rand([batch_size, 3, 224, 224])

# This will work because
# image_batched.shape[dim] / len(device_ids) == image.shape[dim]
output = model_parallel(image_batched)
```

8.32 Developer Guide - PyTorch Neuron (`torch-neuron`) `LSTM` Support

The *torch-neuron* package can support `LSTM` operations and yield high performance on both fixed-length and variable-length sequences. Most network configurations can be supported, with the exception of those that require `PackedSequence` usage outside of `LSTM` or `pad_packed_sequence()` operations. Neuron must guarantee that the shapes can remain fixed throughout the network.

The following sections describe which scenarios can and cannot be supported.

8.32.1 Supported Usage

Fixed-Length Sequences

In normal usage of an `LSTM`, the inputs and outputs are expected to be a fixed size sequence length. This is the most basic usage of an `LSTM` but may not be applicable to applications where the input sequence length may vary.

```
import torch
import torch_neuron

class Network(torch.nn.Module):

    def __init__(self):
        super().__init__()
        self.lstm = torch.nn.LSTM(input_size=3, hidden_size=7)

    def forward(self, inputs):
```

(continues on next page)

(continued from previous page)

```
        output, (ht, ct) = self.lstm(inputs)
        return output, (ht, ct)

# Example Inputs
seq_len, batch_size, input_size = 5, 2, 3
inputs = torch.rand(seq_len, batch_size, input_size)

# Trace
torch_neuron.trace(Network(), (inputs,))
```

Packed Input, Padded Output, *Pre-Sorted* Inputs

A common usage of an `LSTM` is when the input sequence sizes vary according to an input sequence lengths (such as tokens).

For example, the following sentences could result in two different sequence lengths after tokenization:

```
# Input
text = [
   'Hello, sailor',
   'Example',
]

# ... Tokenization ...

# Result
tokens = [
    [101, 7592, 1010, 11803, 102],
    [101, 2742,  102,     0,   0],
]
lengths = [5, 3]
```

Because the lengths are different, the final `LSTM` state will be dependent upon the lengths of each sequence in the batch. Torch provides a way to deal with these types of sequences by densely packing batches into a `PackedSequence`. The most common way this is constructed is by using the `pack_padded_sequence()` utility function prior to feeding inputs into the `LSTM`.

Packing the above sequences would result in the following data and batch size tensors.

```
data = [101, 101, 7592, 2742, 1010, 102, 11803, 102]
batch_sizes = [2, 2, 2, 1, 1]
```

In addition to correctly computing final `LSTM` state, using a packed sequence instead of a padded sequence also improves model performance on CPU. On Neuron, where computation is fixed to the maximum length ahead of time, **this is does not improve performance**.

When an `LSTM` is processing a `PackedSequence`, it must do so in a descending sorted length order. To ensure that sequences are sorted, `pack_padded_sequence()` provides an `enforce_sorted` flag. When `enforce_sorted` is `True`, the input is *already expected* to contain sequences sorted by length in a decreasing order along the batch dimension. Note that this must be enforced in the application-level code but is only relevant when batch size > 1.

The following network can compile successfully because the input and output to the network are guaranteed to be a fixed shape. The input shape is expected to be a padded tensor and the output tensor is expected to be padded to the maximum sequence length using the `pad_packed_sequence()` function call:

```
import torch
import torch_neuron

class Network(torch.nn.Module):

    def __init__(self):
        super().__init__()
        self.lstm = torch.nn.LSTM(input_size=3, hidden_size=7)

    def forward(self, inputs, lengths):
        packed_input = torch.nn.utils.rnn.pack_padded_sequence(
            inputs,
            lengths=lengths,
            enforce_sorted=True,
        )
        packed_result, (ht, ct) = self.lstm(packed_input)
        padded_result, _ = torch.nn.utils.rnn.pad_packed_sequence(packed_result)
        return padded_result, ht, ct

# Example Inputs
seq_len, batch_size, input_size = 5, 2, 3
inputs = torch.rand(seq_len, batch_size, input_size)
lengths = torch.tensor([seq_len] * batch_size)

# Trace
torch_neuron.trace(Network(), (inputs, lengths))
```

Packed Input, Padded Output, *Unsorted* Inputs

When `enforce_sorted` is `False`, the input will be sorted unconditionally. This causes some CPU overhead on Neuron because unsupported operators will be inserted into the graph such as `aten::sort` and `aten::scatter_`. The `aten::lstm` operation can still be supported, but it will be less efficient than when `enforce_sorted` is `True`.

The following code is able to be traced, but results in the sorting operations running on CPU. This is not problematic in this case because the `aten::sort` and `aten::scatter_` are executed on CPU at the very beginning of the graph just prior to Neuron execution.

Like the previous example, the call to `pad_packed_sequence()` ensures that the output is a fixed-shape based on the maximum sequence length.

```
import torch
import torch_neuron

class Network(torch.nn.Module):

    def __init__(self):
        super().__init__()
        self.lstm = torch.nn.LSTM(input_size=3, hidden_size=7)

    def forward(self, inputs, lengths):
        packed_input = torch.nn.utils.rnn.pack_padded_sequence(
            inputs,
            lengths=lengths,
```

(continues on next page)

(continued from previous page)

```
            enforce_sorted=False,
        )
        packed_result, (ht, ct) = self.lstm(packed_input)
        padded_result, _ = torch.nn.utils.rnn.pad_packed_sequence(packed_result)
        return padded_result, ht, ct

# Example Inputs
seq_len, batch_size, input_size = 5, 2, 3
inputs = torch.rand(seq_len, batch_size, input_size)
lengths = torch.tensor([seq_len] * batch_size)

# Trace
trace = torch_neuron.trace(Network(), (inputs, lengths))
```

Packed Inputs, Final Hidden & Cell State Only

When **only** the final `LSTM` hidden & cell state is used, it does not matter if the inputs are packed or unpacked since these state tensors will not vary in size.

```
import torch
import torch_neuron

class Network(torch.nn.Module):

    def __init__(self):
        super().__init__()
        self.lstm = torch.nn.LSTM(input_size=3, hidden_size=7)

    def forward(self, inputs, lengths):
        packed_input = torch.nn.utils.rnn.pack_padded_sequence(
            inputs,
            lengths=lengths,
            enforce_sorted=True,
        )
        packed_output, (ht, ct) = self.lstm(packed_input)
        return ht, ct

# Example Inputs
seq_len, batch_size, input_size = 5, 2, 3
inputs = torch.rand(seq_len, batch_size, input_size)
lengths = torch.tensor([seq_len] * batch_size)

# Trace
trace = torch_neuron.trace(Network(), (inputs, lengths))
```

Note that when the `packed_output` is unused, it does not need to be passed to the `pad_packed_sequence()` to enable the `LSTM` to be compiled.

8.32.2 Unsupported Usage

Neuron does not support the use of a `PackedSequence` outside of the `LSTM` operation and the `pad_packed_sequence()` operation. This is because the shape of a `PackedSequence` can vary depending on the input data. This is incompatible with the Neuron restriction that all tensor sizes must be known at compilation time. When a `PackedSequence` is used only by an `LSTM` or `pad_packed_sequence()` operation, Neuron *can guarantee* the size of the intermediary tensors by padding on behalf of the application.

This means that If the `PackedSequence` is either used by a different operation or returned from the network this would result in all of the `LSTM` operations to be executed on CPU or the network compilation will fail.

`PackedSequence` Returned

The following is unsupported because the `PackedSequence` result of the `LSTM` is returned by the network:

```
class Network(torch.nn.Module):

    def __init__(self):
        super().__init__()
        self.lstm = torch.nn.LSTM(input_size=3, hidden_size=7)

    def forward(self, inputs, lengths):
        packed_input = torch.nn.utils.rnn.pack_padded_sequence(
            inputs,
            lengths=lengths,
            enforce_sorted=False,
        )
        packed_result, (ht, ct) = self.lstm(packed_input)
        return packed_result.data, ht, ct
```

Behavior: In this case, compilation fails and the following warning is generated:

```
Operator "aten::lstm" consuming a PackedSequence input can only be supported when its␣
↪corresponding PackedSequence output is unused or unpacked using "aten::_pad_packed_
↪input". Found usage by "prim::Return"
```

Resolution: To avoid this error, the `packed_result` should be padded prior to being returned from the network by using `pad_packed_sequence()`

Invalid `PackedSequence` Usage

The following is unsupported because the `PackedSequence` result of the `LSTM` is used by a non-LSTM operator:

```
class Network(torch.nn.Module):

    def __init__(self):
        super().__init__()
        self.lstm = torch.nn.LSTM(input_size=3, hidden_size=7)

    def forward(self, inputs, lengths):
        packed_input = torch.nn.utils.rnn.pack_padded_sequence(
            inputs,
            lengths=lengths,
```

(continues on next page)

(continued from previous page)

```
            enforce_sorted=False,
        )
        packed_result, (ht, ct) = self.lstm(packed_input)
        return torch.max(packed_result.data)
```

Behavior: In this case, compilation fails and the following warning is generated:

```
Operator "aten::lstm" consuming a PackedSequence input can only be supported when its␣
↪corresponding PackedSequence output is unused or unpacked using "aten::_pad_packed_
↪input". Found usage by "aten::max"
```

Resolution: To avoid this error, the `packed_result` should be padded prior to being used in the `max()` from the network by using `pad_packed_sequence()`.

8.33 Developer Guide - PyTorch Neuron (`torch-neuron`) Core Placement

This programming guide describes the available techniques and APIs to be able to allocate NeuronCores to a process and place models onto specific NeuronCores. In order of precedence, the current recommendation is to use the following placement techniques:

1. For most regular models, default core placement should be used in conjunction with `NEURON_RT_NUM_CORES` (*Default Core Allocation & Placement*)
2. For more specific core placement for NeuronCore Pipelined models, then `NEURONCORE_GROUP_SIZES` should be used (*NEURONCORE_GROUP_SIZES*).
3. Finally, for even more granular control, then the experimental explicit placement APIs may be used (*Experimental: Explicit Core Placement*).

    * *Issue Summary*
  - *Experimental: Explicit Core Placement*
    * *Example: Manual Core Selection*
    * *Example: Automatic Multicore*
    * *Example: Explicit Replication*

The following guide will assume a machine with 8 NeuronCores:

- NeuronCores will use the notation `nc0`, `nc1`, etc.
- NeuronCore Groups will use the notation `ncg0`, `ncg1` etc.
- Models will use the notation `m0`, `m1` etc.

NeuronCores, NeuronCore Groups, and model allocations will be displayed in the following format:

Note that the actual cores that are visible to the process can be adjusted according to the *Neuron Runtime Configuration*.

8.33.1 NeuronCore Pipeline

A key concept to understand the intent behind certain core placement strategies is NeuronCore Pipelining (See *NeuronCore Pipeline*). NeuronCore Pipelining allows a model to be automatically split into pieces and executed on different NeuronCores.

For most models only 1 NeuronCore will be required for execution. A model will **only** require more than one NeuronCore when using NeuronCore Pipeline. When model pipelining is enabled, the model is split between multiple NeuronCores and data is transferred between them. For example, if the compiler flag `--neuroncore-pipeline-cores 4` is used, this splits the model into 4 pieces to be executed on 4 separate NeuronCores.

8.33.2 Default Core Allocation & Placement

The most basic requirement of an inference application is to be able to place a single model on a single NeuronCore. More complex applications may use multiple NeuronCores or even multiple processes each executing different models. The important thing to note about designing an inference application is that a single NeuronCore will always be allocated to a single process. *Processes do not share NeuronCores*. Different configurations can be used to ensure that an application process has enough NeuronCores allocated to execute its model(s):

- Default: A process will attempt to take ownership of **all NeuronCores** visible on the instance. This should be used when an instance is only running a single inference process since no other process will be allowed to take ownership of any NeuronCores.
- `NEURON_RT_NUM_CORES`: Specify the **number of NeuronCores** to allocate to the process. This places no restrictions on which NeuronCores will be used, however, the resulting NeuronCores will always be contiguous. This should be used in multi-process applications where each process should only use a subset of NeuronCores.
- `NEURON_RT_VISIBLE_CORES`: Specifies exactly **which NeuronCores** are allocated to the process by index. Similar to `NEURON_RT_NUM_CORES`, this can be used in multi-process applications where each process should only use a subset of NeuronCores. This provides more fined-grained controls over the exact NeuronCores that are allocated to a given process.

- NEURONCORE_GROUP_SIZES: Specifies a number of **NeuronCore Groups** which are allocated to the process. This is described in more detail in the *NEURONCORE_GROUP_SIZES* section.

See the *Neuron Runtime Configuration* for more environment variable details.

Example: Default

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc0
m1 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc1
```

With no environment configuration, the process will take ownership of all NeuronCores. In this example, only two of the NeuronCores are used by the process and the remaining are allocated but left idle.

Example: NEURON_RT_NUM_CORES

Environment Setup:

```
export NEURON_RT_NUM_CORES = '2'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc0
m1 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc1
```

Since there is no other process on the instance, only the first 2 NeuronCores will be acquired by the process. Models load in a simple linear order to the least used NeuronCores.

Example: NEURON_RT_VISIBLE_CORES

Environment Setup:

```
export NEURON_RT_VISIBLE_CORES = '4-5'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc4
m1 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc5
```

Unlike NEURON_RT_NUM_CORES, setting the visible NeuronCores allows the process to take control of a specific contiguous set. This allows an application to have a more fine-grained control of where models will be placed.

Example: Overlapping Models

Environment Setup:

```
export NEURON_RT_VISIBLE_CORES = '0-1'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc0
m1 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc0-nc1
m2 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc1
```

This shows how models may share NeuronCores but the default model placement will attempt to evenly distribute NeuronCore usage rather than overlapping all models on a single NeuronCore.

Example: Multiple Processes

Environment Setup:

```
export NEURON_RT_NUM_CORES = '2'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc0
m1 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc1
```

In this example, if the script is run **twice**, the following allocations will be made:

Note that each process will take ownership of as many NeuronCores as is specified by the `NEURON_RT_NUM_CORES` configuration.

8.33.3 NEURONCORE_GROUP_SIZES

Important: The use of explicit core placement should only be used when a specific performance goal is required. By default `torch-neuron` places models on the **least used** NeuronCores. This should be optimal for most applications.

Secondly, `NEURONCORE_GROUP_SIZES` is being deprecated in a future release and should be avoided in favor of newer placement methods. Use `NEURON_RT_NUM_CORES` or `NEURON_RT_VISIBLE_CORES` with default placement if possible (See *Default Core Allocation & Placement*)

In the current release of NeuronSDK, the most well-supported method of placing models onto specific NeuronCores is to use the `NEURONCORE_GROUP_SIZES` environment variable. This will define a set of "NeuronCore Groups" for the application process.

NeuronCore Groups are *contiguous sets of NeuronCores* that are allocated to a given process. Creating groups allows an application to ensure that a model has a defined set of NeuronCores that will always be allocated to it.

Note that NeuronCore Groups *can* be used to allocate non-pipelined models (those requiring exactly 1 NeuronCore) to specific NeuronCores but this is not the primary intended use. The intended use of NeuronCore Groups is to ensure pipelined models (those requiring >1 NeuronCore) have exclusive access to a specific set of contiguous NeuronCores.

In the cases where models are being used *without* NeuronCore Pipeline, the general recommendation is to use default placement (See *Default Core Allocation & Placement*).

The following section demonstrates how `NEURONCORE_GROUP_SIZES` can be used and the issues that may arise.

Example: Single NeuronCore Group

In the example where one model requires 4 NeuronCores, the correct environment configuration would be:

Environment Setup:

```
export NEURONCORE_GROUP_SIZES = '4'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-4-neuron-pipeline-cores.pt')  # Loads to nc0-nc3
```

This is the most basic usage of a NeuronCore Group. The environment setup causes the process to take control of 4 NeuronCores and then the script loads a model compiled with a NeuronCore Pipeline size of 4 to the first group.

Example: Multiple NeuronCore Groups

With more complicated configurations, the intended use of `NEURONCORE_GROUP_SIZES` is to create 1 Group per model with the correct size to ensure that the models are placed on the intended NeuronCores. Similarly, the environment would need to be configured to create a NeuronCore Group for each model:

Environment Setup:

```
export NEURONCORE_GROUP_SIZES = '3,4,1'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-3-neuron-pipeline-cores.pt')  # Loads to nc0-nc2
m1 = torch.jit.load('model-with-4-neuron-pipeline-cores.pt')  # Loads to nc3-nc6
m2 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc7
```

Issue: Overlapping Models with Differing Model Sizes

When multiple models are loaded to a single NeuronCore Group, this can cause unintended inefficiencies. A single model is only intended to span a single NeuronCore Group. Applications with many models of varying sizes can be restricted by NeuronCore Group configurations since the most optimal model layout may require more fine-grained controls.

Environment Setup:

```
export NEURONCORE_GROUP_SIZES = '2,2'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc0-nc1
m1 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc2-nc3
m2 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc0
m3 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc2
m4 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc0
```

Here the `NEURONCORE_GROUP_SIZES` does not generate an optimal layout because placement strictly follows the layout of NeuronCore Groups. A potentially more optimal layout would be to place `m4` onto `nc1`. In this case, since a pipelined model will not be able to have exclusive access to a set of NeuronCores, the default NeuronCore placement (no NeuronCore Groups specified) would more evenly distribute the models.

Also note here that this is an example of where the order of model loads affects which model is assigned to which NeuronCore Group. If the order of the load statements is changed, models may be assigned to different NeuronCore Groups.

Issue: Incompatible Model Sizes

Another problem occurs when attempting to place a model which does not evenly fit into a single group:

Environment Setup:

```
export NEURONCORE_GROUP_SIZES = '2,2'
```

Python Script:

```
import torch
import torch_neuron

m0 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc0-nc1
m1 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc2-nc3
m2 = torch.jit.load('model-with-3-neuron-pipeline-cores.pt')  # Loads to nc0-nc2
```

The model will be placed *across* NeuronCore Groups since there is no obvious group to assign the model to according to the environment variable configuration. Depending on the individual model and application requirements, the placement here may not be optimal.

Issue: Multiple Model Copies

It is common in inference serving applications to use multiple replicas of a single model across different NeuronCores. This allows the hardware to be fully utilized to maximize throughput. In this scenario, when using NeuronCore Groups, the only way to replicate a model on multiple NeuronCores is to create a *new model* object. In the example below, 4 models loads are performed to place a model in each NeuronCore Group.

Environment Setup:

```
export NEURONCORE_GROUP_SIZES = '2,2,2,2'
```

Python Script:

```
import torch
import torch_neuron

models = list()
for _ in range(4):
    model = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')
    models.append(model)
```

The largest consequence of this type of model allocation is that the application code is responsible for routing inference requests to models. There are a variety of ways to implement the inference switching but in all cases routing logic needs to be implemented in the application code.

Issue Summary

The use of `NEURONCORE_GROUP_SIZES` has the following problems:

- **Variable Sized Models**: Models which require crossing NeuronCore Group boundaries may be placed poorly. This means group configuration limits the size of which models can be loaded.
- **Model Load Order**: Models are loaded to NeuronCore Groups greedily. This means that the order of model loads can potentially negatively affect application performance by causing unintentional overlap.
- **Implicit Placement**: NeuronCore Groups cannot be explicitly chosen in the application code.
- **Manual Replication**: When loading multiple copies of a model to different NeuronCore Groups, this requires that multiple model handles are used.

8.33.4 Experimental: Explicit Core Placement

To address the limitations of `NEURONCORE_GROUP_SIZES`, a new set of APIs has been added which allows specific NeuronCores to be chosen by the application code. These can be found in the *Experimental: NeuronCore Placement APIs* documentation.

Example: Manual Core Selection

The most direct usage of the placement APIs is to manually select the start NeuronCore that each model is loaded to. This will automatically use as many NeuronCores as is necessary for that model (1 for most models, >1 for NeuronCore Pipelines models).

Environment Setup:

```
export NEURON_RT_NUM_CORES = '4'
```

Python Script:

```
import torch
import torch_neuron

# NOTE: Order of loads does NOT matter

with torch_neuron.experimental.neuron_cores_context(2):
    m1 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc2-nc3

with torch_neuron.experimental.neuron_cores_context(0):
    m2 = torch.jit.load('model-with-3-neuron-pipeline-cores.pt')  # Loads to nc0-nc2

with torch_neuron.experimental.neuron_cores_context(0):
    m0 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads to nc0-nc1

with torch_neuron.experimental.neuron_cores_context(3):
    m3 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads to nc3
```

Note that this directly solves the `NEURONCORE_GROUP_SIZES` issues of:

- **Variable Sized Models**: Now since models are directly placed on the NeuronCores requested by the application, there is no disconnect between the model sizes and NeuronCore Group sizes.
- **Model Load Order**: Since the NeuronCores are explicitly selected, there is no need to be careful about the order in which models are loaded since they can be placed deterministically regardless of the load order.
- **Implicit Placement**: Similarly, explicit placement means there is no chance that a model will end up being allocated to an incorrect NeuronCore Group.

Example: Automatic Multicore

Using explicit core placement it is possible to replicate a model to multiple NeuronCores simultaneously. This means that a single model object within python can utilize all available NeuronCores (or NeuronCores allocated to the process).

Environment Setup:

```
export NEURON_RT_NUM_CORES = '8'
```

Python Script:

```
import torch
import torch_neuron

with torch_neuron.experimental.multicore_context():
    m0 = torch.jit.load('model-with-1-neuron-pipeline-cores.pt')  # Loads replications␣
↪to nc0-nc7
```

(continues on next page)

(continued from previous page)

This addresses the last NEURONCORE_GROUP_SIZES issue of:

- **Manual Replication**: Since models can be automatically replicated to multiple NeuronCores, this means that applications no longer need to implement routing logic and perform multiple loads.

This API has a secondary benefit that the exact same loading logic can be used on an `inf1.xlarge` or an `inf1.6xlarge`. In either case, it will use all of the NeuronCores that are visible to the process. This means that no special logic needs to be coded for different instance types.

Example: Explicit Replication

Replication is also possible with the `neuron_cores_context()` API. The number of replications is chosen by `replications = floor(nc_count / cores_per_model)`.

Environment Setup:

```
export NEURON_RT_NUM_CORES = '8'
```

Python Script:

```
import torch
import torch_neuron

with torch_neuron.experimental.neuron_cores_context(start_nc=2, nc_count=4):
    m0 = torch.jit.load('model-with-2-neuron-pipeline-cores.pt')  # Loads replications␣
↪to nc2-nc5
```

8.34 PyTorch Neuron (torch-neuron) Supported operators

Current operator lists may be generated with these commands inside python:

```
import torch.neuron
print(*torch.neuron.get_supported_operations(), sep='\n')
```

8.34.1 PyTorch Neuron release [2.5.0.0]

Date: 11/23/2022

Added support for new operators:

- `aten::threshold`
- `aten::roll`
- `aten::instance_norm`
- `aten::amin`
- `aten::amax`

- aten::new_empty
- aten::new_ones
- aten::tril
- aten::triu
- aten::zero_
- aten::all
- aten::broadcast_tensors
- aten::broadcast_to
- aten::logical_and
- aten::logical_not
- aten::logical_or
- aten::logical_xor
- aten::_convolution_mode

Added **limited** support for new operators:

- **LSTM Operations. See:** *Developer Guide - PyTorch Neuron (torch-neuron) LSTM Support*
  - aten::lstm
  - aten::_pack_padded_sequence
  - aten::_pad_packed_sequence
- aten::norm: Supported when p argument is one of (1, 2, inf, -inf, 'fro')

8.34.2 PyTorch Neuron release [2.2.0.0]

Date: 03/25/2022

- Added full support for aten::max_pool2d_with_indices - (Was previously supported only when indices were unused).

8.34.3 PyTorch Neuron release [2.1.7.0]

Date: 01/20/2022

- Added support for new operators:
  - aten::bucketize
  - aten::any
  - aten::remainder
  - aten::clip
  - aten::repeat_interleave
  - aten::tensor_split
  - aten::split_with_sizes
  - aten::isnan

- aten::embedding_renorm_
- aten::dot
- aten::mv
- aten::hardsigmoid
- aten::hardswish
- aten::trunc
- aten::one_hot: Supported when num_classes is known at trace time. The dynamic version of this operation when num_classes = -1 is not supported.
- aten::adaptive_max_pool1d
- aten::adaptive_max_pool2d

PyTorch Neuron Release [2.0.536.0]

- The following are operators with limited support on Neuron. Unlike fully supported operators, these operators are not returned when using torch_neuron.get_supported_operations(). See each operator description for conditional support:
  - aten::max_pool2d_with_indices - Supported when indices outputs are not used by a downstream operation. This allows the operation to be compiled to Neuron when it is equivalent to an aten::max_pool2d.
  - aten::max_pool3d_with_indices - Supported when indices outputs are not used by a downstream operation. This allows the operation to be compiled to Neuron when it is equivalent to an aten::max_pool3d.
  - aten::where - Supported when used as a conditional selection (3-argument variant). Unsupported when used to generate a dynamic list of indices (1-argument variant). See torch.where().

PyTorch Neuron Release [2.0.318.0]

- Added support for new operators:
  - aten::empty_like
  - aten::log
  - aten::type_as
  - aten::movedim
  - aten::einsum
  - aten::argmax
  - aten::min
  - aten::argmin
  - aten::abs
  - aten::cos
  - aten::sin
  - aten::linear
  - aten::pixel_shuffle

- aten::group_norm
- aten::_weight_norm

PyTorch Neuron Release [1.5.21.0]

No change

PyTorch Neuron Release [1.5.7.0]

Added:

```
aten::erf
prim::DictConstruct
```

PyTorch Neuron Release [1.4.1.0]

No change

PyTorch Neuron Release [1.3.5.0]

Added:

```
aten::numel
aten::ones_like
aten::reciprocal
aten::topk
```

PyTorch Neuron Release [1.2.16.0]

No change

PyTorch Neuron Release [1.2.15.0]

No change

PyTorch Neuron Release [1.2.3.0]

Added:

```
aten::silu
aten::zeros_like
```

PyTorch Neuron Release [1.1.7.0]

Added:

```
aten::_shape_as_tensor
aten::chunk
aten::empty
aten::masked_fill
```

PyTorch Neuron Release [1.0.24045.0]

Added:

```
aten::__and__
aten::bmm
aten::clone
aten::expand_as
aten::fill_
aten::floor_divide
aten::full
aten::hardtanh
aten::hardtanh_
aten::le
aten::leaky_relu
aten::lt
aten::mean
aten::ne
aten::softplus
aten::unbind
aten::upsample_bilinear2d
```

PyTorch Neuron Release [1.0.1720.00]

Added:

```
aten::constant_pad_nd
aten::meshgrid
```

PyTorch Neuron Release [1.0.1532.0]

Added:

```
aten::ones
```

PyTorch Neuron Release [1.0.1522.0]

- No change

PyTorch Neuron Release [1.0.1386.0]

Added the following instructions. Please note, primitives are included in this list from this release.

```
aten::ceil
aten::clamp
aten::eq
aten::exp
aten::expand_as
aten::flip
aten::full_like
aten::ge
aten::gt
aten::log2
aten::log_softmax
aten::max
aten::neg
aten::relu
aten::rsqrt
aten::scalarImplicit
aten::sqrt
aten::squeeze
aten::stack
aten::sub
aten::sum
aten::true_divide
aten::upsample_nearest2d
prim::Constant
prim::GetAttr
prim::ImplicitTensorToNum
prim::ListConstruct
prim::ListUnpack
prim::NumToTensor
prim::TupleConstruct
prim::TupleUnpack
```

PyTorch Neuron Release [1.0.1168.0]

Added `aten::ScalarImplicit`

PyTorch Neuron Release [1.0.1001.0]

Added

```
aten::detach
aten::floor
aten::gelu
aten::pow
aten::sigmoid
aten::split
```

Removed (Reasons given alongside)

```
aten::embedding (does not meet performance criteria)
aten::erf (error function does not meet accuracy criteria)
aten::tf_dtype_from_torch (internal support function, not an operator)
```

PyTorch Neuron Release [1.0.825.0]

PyTorch Neuron Release [1.0.763.0]

- Please note. Starting with this release we will not publish primitives (prim::).
- Previous release inaccurately listed these operators as aten ops, they are not.

```
aten::tf_broadcastable_slice
aten::tf_padding
```

The following new operators are added in this release.

```
aten::Int
aten::arange
aten::contiguous
aten::div
aten::embedding
aten::erf
aten::expand
aten::eye
aten::index_select
aten::layer_norm
aten::matmul
aten::mm
aten::permute
aten::reshape
aten::rsub
aten::select
aten::size
aten::slice
```

(continues on next page)

(continued from previous page)

```
aten::softmax
aten::tf_dtype_from_torch
aten::to
aten::transpose
aten::unsqueeze
aten::view
aten::zeros
```

These operators were already supported previously (removing the two that were included by mistake)

```
aten::_convolution
aten::adaptive_avg_pool2d
aten::add
aten::add_
aten::addmm
aten::avg_pool2d
aten::batch_norm
aten::cat
aten::dimension_value
aten::dropout
aten::flatten
aten::max_pool2d
aten::mul
aten::relu_
aten::t
aten::tanh
aten::values
prim::Constant
prim::GetAttr
prim::ListConstruct
prim::ListUnpack
prim::TupleConstruct
prim::TupleUnpack
```

PyTorch Neuron Release [1.0.672.0]

No change

8.35 Troubleshooting Guide for PyTorch Neuron (`torch-neuron`)

8.35.1 General Torch-Neuron issues

If you see an error about "Unknown builtin op: neuron::forward_1" like below, please ensure that import line "import torch_neuron" (to register the Neuron custom operation) is in the inference script before using torch.jit.load.

```
Unknown builtin op: neuron::forward_1.
Could not find any similar ops to neuron::forward_1. This op may not exist or may not be␣
↪currently supported in TorchScript.
```

8.35.2 TorchVision related issues

If you encounter an error like below, it is because latest torchvision version >= 0.7 is not compatible with Torch-Neuron 1.5.1. Please downgrade torchvision to version 0.6.1:

```
E   AttributeError: module 'torch.jit' has no attribute '_script_if_tracing'
```

8.35.3 torch.jit.trace issues

The /neuron-guide/neuron-frameworks/pytorch-neuron/api-compilation-python-api.rst uses the PyTorch `torch.jit.trace()` function to generate `ScriptModule` models for execution on Inferentia. Due to that, to execute your PyTorch model on Inferentia it must be torch-jit-traceable, otherwise you need to make sure your model is torch-jit-traceable. You can try modifying your underlying PyTorch model code to make it traceable. If it's not possible to change your model code, you can *write a wrapper around your model* that makes it torch-jit-traceable to compile it for Inferentia.

Please visit `torch.jit.trace()` to review the properties that a model must have to be torch-jit-traceable. The PyTorch-Neuron trace API *`torch_neuron.trace()`* accepts `**kwargs` for `torch.jit.trace()`. For example, you can use the `strict=False` flag to *compile models with dictionary outputs*.

Compiling models with outputs that are not torch-jit-traceable

To enable compilation of models with non torch-jit-traceable outputs, you can use a technique that involves writing a wrapper that converts the model's output into a form that is torch-jit-traceable. You can then compile the wrapped model for Inferentia using `torch_neuron.trace()`.

The following example uses a wrapper to compile a model with non torch-jit-traceable outputs. This model cannot be compiled for Inferentia in its current form because it outputs a list of tuples and tensors, which is not torch-jit-traceable.

```
import torch
import torch_neuron
import torch.nn as nn

class Model(nn.Module):
    def __init__(self):
        super(Model, self).__init__()
        self.conv = nn.Conv2d(1, 1, 3)

    def forward(self, x):
        a = self.conv(x) + 1
        b = self.conv(x) + 2
        c = self.conv(x) + 3
        # An output that is a list of tuples and tensors is not torch-traceable
        return [(a, b), c]

model = Model()
model.eval()

inputs = torch.rand(1, 1, 3, 3)

# Try to compile the model
model_neuron = torch.neuron.trace(model, inputs) # ERROR: This cannot be traced, we must␣
↪change the output format
```

To compile this model for Inferentia, we can write a wrapper around the model to convert its outputs into a tuple of tensors, which is torch-jit-traceable.

```
class NeuronCompatibilityWrapper(nn.Module):
    def __init__(self):
        super(NeuronCompatibilityWrapper, self).__init__()
        self.model = Model()

    def forward(self, x):
        out = self.model(x)
        # An output that is a tuple of tuples and tensors is torch-jit-traceable
        return tuple(out)
```

Now, we can successfully compile the model for Inferentia using the `NeuronCompatibilityWrapper` wrapper as follows:

```
model = NeuronCompatibilityWrapper()
model.eval()

# Compile the traceable wrapped model
model_neuron = torch.neuron.trace(model, inputs)
```

If the model's outputs must be in the original form, a second wrapper can be used to transform the outputs after compilation for Inferentia. The following example uses the `OutputFormatWrapper` wrapper to convert the compiled model's output back into the original form of a list of tuples and tensors.

```
class OutputFormatWrapper(nn.Module):
    def __init__(self):
        super(OutputFormatWrapper, self).__init__()
        self.traceable_model = NeuronCompatibilityWrapper()

    def forward(self, x):
        out = self.traceable_model(x)
        # Return the output in the original format of Model()
        return list(out)

model = OutputFormatWrapper()
model.eval()

# Compile the traceable wrapped model
model.traceable_model = torch.neuron.trace(model.traceable_model, inputs)
```

Compiling a submodule in a model that is not torch-jit-traceable

The following example shows how to compile a submodule that is part of a non torch-jit-traceable model. In this example, the top-level model `Outer` uses a dynamic flag, which is not torch-jit-traceable. However, the submodule `Inner` is torch-jit-traceable and can be compiled for Inferentia.

```
import torch
import torch_neuron
import torch.nn as nn

class Inner(nn.Module) :
    def __init__(self):
        super().__init__()
        self.conv = nn.Conv2d(1, 1, 3)

    def forward(self, x):
        return self.conv(x) + 1

class Outer(nn.Module):
    def __init__(self):
        super().__init__()
        self.inner = Inner()

    def forward(self, x, add_offset: bool = False):
        base = self.inner(x)
        if add_offset:
            return base + 1
        return base

model = Outer()
inputs = torch.rand(1, 1, 3, 3)
```

(continues on next page)

(continued from previous page)

```
# Compile the traceable wrapped submodule
model.inner = torch.neuron.trace(model.inner, inputs)

# TorchScript the model for serialization
script = torch.jit.script(model)
torch.jit.save(script, 'model.pt')

loaded = torch.jit.load('model.pt')
```

Alternatively, for usage scenarios in which the model configuration is static during inference, the dynamic flags can be hardcoded in a wrapper to make the model torch-jit-traceable and enable compiling the entire model for Inferentia. In this example, we assume the `add_offset` flag is always `True` during inference, so we can hardcode this conditional path in the `Static` wrapper to remove the dynmaic behavior and compile the entire model for Inferentia.

```
class Static(nn.Module):
    def __init__(self):
        super().__init__()
        self.outer = Outer()

    def forward(self, x):
        # hardcode `add_offset=True`
        output = self.outer(x, add_offset=True)
        return output

model = Static()

# We can now compile the entire model because `add_offset=True` is hardcoded in the␣
↪Static wrapper
model_neuron = torch.neuron.trace(model, inputs)
```

This document lists the release notes for the Pytorch-Neuron package.

8.36.1 Known Issues and Limitations - Updated 11/23/2022

Min & Max Accuracy

The index outputs of the `aten::argmin`, `aten::argmax`, `aten::min`, and `aten::max` operator implementations are sensitive to precision. For models that contain these operators and have `float32` inputs, we recommend using the `--fp32-cast=matmult --fast-math no-fast-relayout` compiler option to avoid numerical imprecision issues. Additionally, the `aten::min` and `aten::max` operator implementations do not currently support `int64` inputs when `dim=0`. For more information on precision and performance-accuracy tuning, see *Mixed precision and performance-accuracy tuning (neuron-cc)*.

Python 3.5

If you attempt to import torch.neuron from Python 3.5 you will see this error in 1.1.7.0 - please use Python 3.6 or greater:

```
File "/tmp/install_test_env/lib/python3.5/site-packages/torch_neuron/__init__.py", line␣
↪29
  f'Invalid dependency version torch=={torch.__version__}. '
                                                         ^
SyntaxError: invalid syntax
```

- Torchvision has dropped support for Python 3.5
- HuggingFace transformers has dropped support for Python 3.5

Torchvision

When versions of `torchvision` and `torch` are mismatched, this can result in exceptions when compiling `torchvision` based models. Specific versions of `torchvision` are built against each release of `torch`. For example:

- `torch==1.5.1` matches `torchvision==0.6.1`
- `torch==1.7.1` matches `torchvision==0.8.2`
- etc.

Simultaneously installing both `torch-neuron` and `torchvision` is the recommended method of correctly resolving versions.

Dynamic Batching

Dynamic batching does not work properly for some models that use the `aten::size` operator. When this issue occurs, the input batch sizes are not properly recorded at inference time, resulting in an error such as:

```
RuntimeError: The size of tensor a (X) must match the size of tensor b (Y) at non-
↪singleton dimension 0.
```

This error typically occurs when `aten::size` operators are partitioned to CPU. We are investigating a fix for this issue.

8.36.2 PyTorch Neuron release [2.5.0.0]

Date: 11/23/2022

New in this release

- Added PyTorch 1.12 support
- Added Python 3.8 support
- Added new operators support. See *PyTorch Neuron (torch-neuron) Supported operators*
- Added support for `aten::lstm`. See: *Developer Guide - PyTorch Neuron (torch-neuron) LSTM Support*
- **Improved logging:**
  - Improved error messages for specific compilation failure modes, including out-of-memory errors

  - Added a warning to show the code location of `prim::PythonOp` operations
  - Removed overly-verbose tracing messages
  - Added improved error messages for `neuron-cc` and `tensorflow` dependency issues
  - Added more debug information when an invalid dynamic batching configuration is used
- Added new experimental explicit NeuronCore placement API. See: *Experimental: NeuronCore Placement APIs*
- Added new guide for NeuronCore placement. See: *Developer Guide - PyTorch Neuron (torch-neuron) Core Placement*
- Improved `torch_neuron.trace()` performance when using large graphs
- Reduced host memory usage of loaded models in `libtorchneuron.so`
- Added `single_fusion_ratio_threshold` argument to `torch_neuron.trace()` to give more fine-grained control of partitioned graphs

Bug fixes

- Improved handling of tensor mutations which previously caused accuracy issues on certain models (i.e. yolor, yolov5)
- Fixed an issue where `inf` and `-inf` values would cause unexpected `NaN` values. This could occur with newer versions of `transformers`
- Fixed an issue where `torch.neuron.DataParallel()` would not fully utilize all NeuronCores for specific batch sizes
- **Fixed and improved operators:**
  - `aten::upsample_bilinear2d`: Improved error messages in cases where the operation cannot be supported
  - `aten::_convolution`: Added support for `output_padding` argument
  - `aten::div`: Added support for `rounding_mode` argument
  - `aten::sum`: Fixed to handle non-numeric data types
  - `aten::expand`: Fixed to handle scalar tensors
  - `aten::permute`: Fixed to handle negative indices
  - `aten::min`: Fixed to support more input types
  - `aten::max`: Fixed to support more input types
  - `aten::max_pool2d`: Fixed to support both 3-dimensional and 4-dimensional input tensors
  - `aten::Int`: Fixed an issue where long values would incorrectly lose precision
  - `aten::constant_pad_nd`: Fixed to correctly use non-0 padding values
  - `aten::pow`: Fixed to support more input types & values
  - `aten::avg_pool2d`: Added support for `count_include_pad` argument. Added support for `ceil_mode` argument if padding isn't specified
  - `aten::zero`: Fixed to handle scalars correctly
  - `prim::Constant`: Fixed an issue where `-inf` was incorrectly handled
  - Improved handling of scalars in arithmetic operators

8.36.3 PyTorch Neuron release [2.3.0.0]

Date: 04/29/2022

New in this release

- Added support PyTorch 1.11.
- Updated PyTorch 1.10 to version 1.10.2.
- End of support for torch-neuron 1.5, see eol-pt-15.
- Added support for new operators:
  - `aten::masked_fill_`
  - `aten::new_zeros`
  - `aten::frobenius_norm`

Bug fixes

- Improved `aten::gelu` accuracy
- Updated `aten::meshgrid` to support optional indexing argument introduced in `torch 1.10` , see PyTorch issue 50276

8.36.4 PyTorch Neuron release [2.2.0.0]

Date: 03/25/2022

New in this release

- Added full support for `aten::max_pool2d_with_indices` - (Was previously supported only when indices were unused).
- Added new torch-neuron packages compiled with `-D_GLIBCXX_USE_CXX11_ABI=1`, the new packages support PyTorch 1.8, PyTorch 1.9, and PyTorch 1.10. To install the additional packages compiled with `-D_GLIBCXX_USE_CXX11_ABI=1` please change the package repo index to `https://pip.repos.neuron.amazonaws.com (https://pip.repos.neuron.amazonaws.com/)/cxx11/`

8.36.5 PyTorch Neuron release [2.1.7.0]

Date: 01/20/2022

New in this release

- Added PyTorch 1.10 support
- Added new operators support, see *PyTorch Neuron (torch-neuron) Supported operators*
- Updated `aten::_convolution` to support 2d group convolution
- Updated `neuron::forward` operators to allocate less dynamic memory. This can increase performance on models with many input & output tensors.
- Updated `neuron::forward` to better handle batch sizes when `dynamic_batch_size=True`. This can increase performance at inference time when the input batch size is exactly equal to the traced model batch size.

Bug fixes

- Added the ability to `torch.jit.trace` a `torch.nn.Module` where a submodule has already been traced with `torch_neuron.trace()` on a CPU-type instance. Previously, if this had been executed on a CPU-type instance, an initialization exception would have been thrown.
- Fixed `aten::matmul` behavior on 1-dimensional by n-dimensional multiplies. Previously, this would cause a validation error.
- Fixed binary operator type promotion. Previously, in unusual situations, operators like `aten::mul` could produce incorrect results due to invalid casting.
- Fixed `aten::select` when index was -1. Previously, this would cause a validation error.
- Fixed `aten::adaptive_avg_pool2d` padding and striding behavior. Previously, this could generate incorrect results with specific configurations.
- Fixed an issue where dictionary inputs could be incorrectly traced when the tensor values had gradients.

8.36.6 PyTorch Neuron release [2.0.536.0]

Date: 01/05/2022

New in this release

- Added new operator support for specific variants of operations (See *PyTorch Neuron (torch-neuron) Supported operators*)
- Added optional `optimizations` keyword to `torch_neuron.trace()` which accepts a list of `Optimization` passes.

8.36.7 PyTorch Neuron release [2.0.468.0]

Date: 12/15/2021

New in this release

- Added support for `aten::cumsum` operation.
- Fixed `aten::expand` to correctly handle adding new dimensions.

8.36.8 PyTorch Neuron release [2.0.392.0]

Date: 11/05/2021

- Updated Neuron Runtime (which is integrated within this package) to `libnrt 2.2.18.0` to fix a container issue that was preventing the use of containers when /dev/neuron0 was not present. See details here neuron-runtime-release-notes.

8.36.9 PyTorch Neuron release [2.0.318.0]

Date: 10/27/2021

New in this release

- PyTorch Neuron 1.x now support Neuron Runtime 2.x (`libnrt.so` shared library) only.

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.
  - Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

- Introducing PyTorch 1.9.1 support (support for `torch==1.9.1`)
- Added `torch_neuron.DataParallel`, see ResNet-50 tutorial *[html]* and *Data Parallel Inference on Torch Neuron* application note.
- Added support for tracing on GPUs
- Added support for `ConvTranspose1d`
- Added support for new operators:
  - `aten::empty_like`
  - `aten::log`
  - `aten::type_as`
  - `aten::movedim`
  - `aten::einsum`
  - `aten::argmax`
  - `aten::min`
  - `aten::argmin`

  - aten::abs
  - aten::cos
  - aten::sin
  - aten::linear
  - aten::pixel_shuffle
  - aten::group_norm
  - aten::_weight_norm
- Added torch_neuron.is_available()

Resolved Issues

- Fixed a performance issue when using both the dynamic_batch_size=True trace option and --neuron-core-pipeline compiler option. Dynamic batching now uses OpenMP to execute pipeline batches concurrently.
- Fixed torch_neuron.trace issues:
  - Fixed a failure when the same submodule was traced with multiple inputs
  - Fixed a failure where some operations would fail to be called with the correct arguments
  - Fixed a failure where custom operators (torch plugins) would cause a trace failure
- Fixed variants of aten::upsample_bilinear2d when scale_factor=1
- Fixed variants of aten::expand using dim=-1
- Fixed variants of aten::stack using multiple different input data types
- Fixed variants of aten::max using indices outputs

8.36.10 [1.8.1.1.5.21.0]

Date: 08/12/2021

Summary

- Minor updates.

8.36.11 [1.8.1.1.5.7.0]

Date: 07/02/2021

Summary

- Added support for dictionary outputs using `strict=False` flag. See /neuron-guide/neuron-frameworks/pytorch-neuron/troubleshooting-guide.rst.
- Updated `aten::batch_norm` to correctly implement the `affine` flag.
- Added support for `aten::erf` and `prim::DictConstruct`. See *PyTorch Neuron (torch-neuron) Supported operators*.
- Added dynamic batch support. See /neuron-guide/neuron-frameworks/pytorch-neuron/api-compilation-python-api.rst.

8.36.12 [1.8.1.1.4.1.0]

Date: 5/28/2021

Summary

- Added support for PyTorch 1.8.1
  - Models compatibility
    - Models compiled with previous versions of PyTorch Neuron (<1.8.1) are compatible with PyTorch Neuron 1.8.1.
    - Models compiled with PyTorch Neuron 1.8.1 are not backward compatible with previous versions of PyTorch Neuron (<1.8.1) .
  - Updated tutorials to use Hugging Face Transformers 4.6.0.
  - Added a new set of forward operators (forward_v2)
  - Host memory allocation when loading the same model on multiple NeuronCores is significantly reduced
  - Fixed an issue where models would not deallocate all memory within a python session after being garbage collected.
  - Fixed a TorchScript/C++ issue where loading the same model multiple times would not use multiple NeuronCores by default.
- Fixed logging to no longer configure the root logger.
- Removed informative messages that were produced during compilations as warnings. The number of warnings reduced significantly.
- Convolution operator support has been extended to include ConvTranspose2d variants.
- Reduce the amount of host memory usage during inference.

8.36.13 [1.7.1.1.3.5.0]

Date: 4/30/2021

Summary

- ResNext models now functional with new operator support
- Yolov5 support refer to https://github.com/aws/aws-neuron-sdk/issues/253 note https://github.com/ultralytics/yolov5/pull/2953 which optimized YoloV5 for AWS Neuron
- Convolution operator support has been extended to include most Conv1d and Conv3d variants
- New operator support. Please see *PyTorch Neuron (torch-neuron) Supported operators* for the complete list of operators.

8.36.14 [1.7.1.1.2.16.0]

Date: 3/4/2021

Summary

- Minor enhancements.

8.36.15 [1.7.1.1.2.15.0]

Date: 2/24/2021

Summary

- Fix for CVE-2021-3177.

8.36.16 [1.7.1.1.2.3.0]

Date: 1/30/2021

Summary

- Made changes to allow models with -inf scalar constants to correctly compile
- Added new operator support. Please see *PyTorch Neuron (torch-neuron) Supported operators* for the complete list of operators.

8.36.17 [1.1.7.0]

Date: 12/23/2020

Summary

- We are dropping support for Python 3.5 in this release
- torch.neuron.trace behavior will now throw a RuntimeError in the case that no operators are compiled for neuron hardware
- torch.neuron.trace will now display compilation progress indicators (dots) as default behavior (neuron-cc must updated to the December release to greater to see this feature)
- Added new operator support. Please see *PyTorch Neuron (torch-neuron) Supported operators* for the complete list of operators.
- Extended the BERT pretrained tutorial to demonstrate execution on multiple cores and batch modification, updated the tutorial to accomodate changes in the Hugging Face Transformers code for version 4.0
- Added a tutorial for torch-serve which extends the BERT tutorial
- Added support for PyTorch 1.7

8.36.18 [1.0.1978.0]

Date: 11/17/2020

Summary

- Fixed bugs in comparison operators, and added remaining variantes (eq, ne, gt, ge, lt, le)
- Added support for prim::PythonOp - note that this must be run on CPU and not Neuron. We recommend you replace this code with PyTorch operators if possible
- Support for a series of new operators. Please see *PyTorch Neuron (torch-neuron) Supported operators* for the complete list of operators.
- Performance improvements to the runtime library
- Correction of a runtime library bug which caused models with large tensors to generate incorrect results in some cases

8.36.19 [1.0.1721.0]

Date: 09/22/2020

Summary

- Various minor improvements to the Pytorch autopartitioner feature
- Support for the operators aten::constant_pad_nd, aten::meshgrid
- Improved performance on various torchvision models. Of note are resnet50 and vgg16

8.36.20 [1.0.1532.0]

Date: 08/08/2020

Summary

- Various minor improvements to the Pytorch autopartitioner feature
- Support for the aten:ones operator

8.36.21 [1.0.1522.0]

Date: 08/05/2020

Summary

Various minor improvements.

8.36.22 [1.0.1386.0]

Date: 07/16/2020

Summary

This release adds auto-partitioning, model analysis and PyTorch 1.5.1 support, along with a number of new operators

Major New Features

- Support for Pytorch 1.5.1
- Introduce an automated operator device placement mechanism in torch.neuron.trace to run sub-graphs that contain operators that are not supported by the neuron compiler in native PyTorch. This new mechanism is on by default and can be turned off by adding argument fallback=False to the compiler arguments.
- Model analysis to find supported and unsupported operators in a model

Resolved Issues

8.36.23 [1.0.1168.0]

Date 6/11/2020

Summary

Major New Features

Resolved Issues

Known Issues and Limitations

8.36.24 [1.0.1001.0]

Date: 5/11/2020

Summary

Additional PyTorch operator support and improved support for model saving and reloading.

Major New Features

- Added Neuron Compiler support for a number of previously unsupported PyTorch operators. Please see :ref:`neuron-cc-ops-pytorch`for the complete list of operators.
- Add support for torch.neuron.trace on models which have previously been saved using torch.jit.save and then reloaded.

Resolved Issues

Known Issues and Limitations

8.36.25 [1.0.825.0]

Date: 3/26/2020

Summary

Major New Features

Resolved Issues

Known Issues and limitations

8.36.26 [1.0.763.0]

Date: 2/27/2020

Summary

Added Neuron Compiler support for a number of previously unsupported PyTorch operators. Please see *PyTorch Neuron (torch-neuron) Supported operators* for the complete list of operators.

Major new features

- None

Resolved issues

- None

8.36.27 [1.0.672.0]

Date: 1/27/2020

Summary

Major new features

Resolved issues

- Python 3.5 and Python 3.7 are now supported.

Known issues and limitations

Other Notes

8.36.28 [1.0.627.0]

Date: 12/20/2019

Summary

This is the initial release of torch-neuron. It is not distributed on the DLAMI yet and needs to be installed from the neuron pip repository.

Note that we are currently using a TensorFlow as an intermediate format to pass to our compiler. This does not affect any runtime execution from PyTorch to Neuron Runtime and Inferentia. This is why the neuron-cc installation must include [tensorflow] for PyTorch.

Major new features

Resolved issues

Known issues and limitations

Models TESTED

The following models have successfully run on neuron-inferentia systems

1. SqueezeNet
2. ResNet50
3. Wide ResNet50

Pytorch Serving

In this initial version there is no specific serving support. Inference works correctly through Python on Inf1 instances using the neuron runtime. Future releases will include support for production deployment and serving of models

Profiler support

Profiler support is not provided in this initial release and will be available in future releases

Automated partitioning

Automatic partitioning of graphs into supported and non-supported operations is not currently supported. A tutorial is available to provide guidance on how to manually parition a model graph. Please see pytorch-manual-partitioning-jn-tutorial

PyTorch dependency

Currently PyTorch support depends on a Neuron specific version of PyTorch v1.3.1. Future revisions will add support for 1.4 and future releases.

Trace behavior

In order to trace a model it must be in evaluation mode. For examples please see *ResNet50 model for Inferentia*

Six pip package is required

The Six package is required for the torch-neuron runtime, but it is not modeled in the package dependencies. This will be fixed in a future release.

Multiple NeuronCore support

If the num-neuroncores options is used the number of cores must be manually set in the calling shell environment variable for compilation and inference.

For example: Using the keyword argument compiler_args=['—num-neuroncores', '4'] in the trace call, requires NEURONCORE_GROUP_SIZES=4 to be set in the environment at compile time and runtime

CPU execution

At compilation time a constant output is generated for the purposes of tracing. Running inference on a non neuron instance will generate incorrect results. This must not be used. The following error message is generated to stderr:

```
Warning: Tensor output are ** NOT CALCULATED ** during CPU execution and only
indicate tensor shape
```

Other notes

- Python version(s) supported:
  - 3.6
- Linux distribution supported:
  - DLAMI Ubuntu 18 and Amazon Linux 2 (using Python 3.6 Conda environments)
  - Other AMIs based on Ubuntu 18
  - For Amazon Linux 2 please install Conda and use Python 3.6 Conda environment

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`, `Trn1`

This document is relevant for: `Inf1`, `Trn1`

CHAPTER

NINE

TENSORFLOW NEURON

TensorFlow Neuron unlocks high-performance and cost-effective deep learning acceleration on AWS Trainium-based and Inferentia-based Amazon EC2 instances.

TensorFlow Neuron enables native TensorFlow models to be accelerated on Neuron devices, so you can use your existing framework application and get started easily with minimal code changes.

Inference

Setup Guide for Inf1

This document is relevant for: `Inf1`

9.1 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

9.1.1 Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

TensorFlow 2.8.2

Ubuntu 18 AMI/Ubuntu 20 AMI

9.1.2 Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

TensorFlow 2.8.2

↪include latest Neuron versions
# To update to latest Neuron version, follow "Update to latest release" instruction on␣
↪Neuron documentation

# Activate TensorFlow
source activate aws_neuron_tensorflow_p36
```

Amazon Linux DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Neuron is pre-installed on Deep Learning AMI (DLAMI), latest DLAMI version may not␣
↪include latest Neuron versions
# To update to latest Neuron version, follow "Update to latest release" instruction on␣
↪Neuron documentation

# Activate TensorFlow
source activate aws_neuron_tensorflow_p36
```

9.1.3 Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

TensorFlow 2.8.2

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

9.2 Update to latest TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

9.2.1 Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

TensorFlow 2.8.0

Ubuntu AMI

9.2.2 Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

TensorFlow 2.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

pip install --upgrade tensorflow-neuron==1.15.5.* neuron-cc "protobuf"
```

9.2.3 Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

TensorFlow 2.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Update OS packages
sudo apt-get update -y

9.3.1 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

TensorFlow 2.8.0

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

TensorFlow 2.8.0
