This document is relevant for: `Inf1`

9.3.2 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

TensorFlow 2.7.1

(continued from previous page)

```
sudo yum versionlock delete tensorflow-model-server-neuron
sudo yum install tensorflow-model-server-neuron-1.15.0.2.2.0.0 -y
```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

TensorFlow 2.7.1

Ubuntu AMI

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.2.0.0 neuron-cc==1.10.3.0 "protobuf"
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

9.3.3 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.1.14.0 neuron-cc==1.9.1.0 "protobuf"
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

This document is relevant for: `Inf1`

9.3.4 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.1.14.0 neuron-cc==1.9.1.0 "protobuf"
```

Amazon Linux AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Install Python venv and activate Python virtual environment to install
# Neuron pip packages.
sudo yum install -y python3.6-venv gcc-c++
python3.6 -m venv tensorflow_venv
source tensorflow_venv/bin/activate
pip install -U pip

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.1.14.0 neuron-cc==1.9.1.0 "protobuf"
```

Ubuntu DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Activate TensorFlow
source activate aws_neuron_tensorflow_p36

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.1.14.0 neuron-cc==1.9.1.0 "protobuf"
```

Amazon Linux DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Activate TensorFlow
source activate aws_neuron_tensorflow_p36

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.1.14.0 neuron-cc==1.9.1.0 "protobuf"
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

TensorFlow 2.5.2

Ubuntu AMI

9.3.5 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

TensorFlow 2.5.2

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

pip install tensorflow-neuron==1.15.5.2.1.6.0 neuron-cc==1.9.1.0 "protobuf"
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

9.3.6 Install TensorFlow Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

TensorFlow 2.5.2

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.2.0.5.0 neuron-cc==1.8.5.0 "protobuf"
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

TensorFlow 2.5.2

Ubuntu AMI

9.3.7 Install TensorFlow Neuron (Neuron 1.15.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

TensorFlow 2.5.0

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

TensorFlow 2.5.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

9.3.8 Install TensorFlow Neuron (Neuron 1.15.1)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

#Install Neuron TensorFlow
pip install tensorflow-neuron==1.15.5.1.6.8.0 neuron-cc==1.6.13.0 "protobuf"
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

TensorFlow 2.5.0

Ubuntu AMI

9.3.9 Install TensorFlow Neuron (Neuron 1.15.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

TensorFlow 2.5.0

Ubuntu AMI

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

TensorFlow 2.5.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

TensorFlow 2.5.0

9.3.10 Install TensorFlow Neuron (Neuron 1.14.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

TensorFlow 1.15.5

Ubuntu AMI

9.4 Running OpenPose on Inferentia

9.4.1 Note: this tutorial runs on tensorflow-neuron 1.x only

9.4.2 Introduction:

In this tutorial we will compile and deploy Openpose model for Inferentia. This jupyter notebook should run on an inf1.6xlarge instance for compilation and inference. The inference part of this tutorial requires inf1.6xlarge and not the compilation itself. For simplicity we will run this tutorial on a single instance but in real life scenario the compilation can be done on a compute c5.4xlarge instance and the deployment on the inf1 instance family.

In this tutorial we provide two main sections: 1. Compile the OpenPose model on inf1x6large. 2. Infer the same compiled model on inf1x6large.

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the Tensorflow Installation Guide. You can select the Kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

9.4.3 Acknowledgement:

Many thanks to https://github.com/ildoonet for providing pretrained model as well as the image preprocessing/pose estimating infrastructure.

9.4.4 Download tensorflow pose net frozen graph.

[ ]:
```
!wget -c --tries=2 $( wget -q -O - http://www.mediafire.com/file/qlzzr20mpocnpa3/graph_
↪opt.pb | grep -o 'http*://download[^"]*' | tail -n 1 ) -O graph_opt.pb
```

9.4.5 Compile

Compile the pose net frozen graph into AWS Neuron compatible form. Network input image resolution is adjustable with argument –net_resolution (e. g., –net_resolution=656x368). The compiled model can accept arbitrary batch size input at runtime.

[ ]:
```
"""
Usage: python convert_graph_opt.py /path/to/graph_opt.pb /path/to/graph_opt_neuron.pb

9.4.6 Deploy

Using same instance to deploy the model. In case of different deployment instance, launch a deployment inf1 instance and copy the AWS Neuron optimized tensorflow frozen graph graph_opt_neuron_656x368.pb to the deployment inf1 instance. The smallest instance type inf1.xlarge is sufficient for this demo.

Your graph_opt_neuron_656x368.pb can now be plugged into https://github.com/ildoonet seemlessly if you have tensorflow-neuron installed. When it is used at runtime, please ensure that the image resolution is the same as compile-time image resolution, i. e., 656x368.

Measure performance on the compiled frozen graph using dummy inputs.

    the following function call before running inferences:
    `tfn.measure_performance()`
    Then latency/throughput report will be generated when the process terminates.
    Alternatively, it is possible to use `tfn.measure_performance` programmatically
    as a context manager. Performance measurement will be done for all inferences
    happening under this context. Report will be displayed as INFO level log when exiting
    the context. It is also possible to obtain a JSON format report in Python.
    For example:
    ```
    with tfn.measure_performance() as perf:
        ... (run some inferences) ...
    report_json = perf.report()
    report_full_json = perf.report(verbosity=1)
    ```
    """
```

9.5 Running ResNet50 on Inferentia

9.5.1 Note: this tutorial runs on tensorflow-neuron 1.x only

9.5.2 Introduction:

In this tutorial we will compile and deploy ResNet50 model for Inferentia. In this tutorial we provide two main sections: 1. Compile the ResNet50 model. 2. Infer the same compiled model.

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the Tensorflow Installation Guide. You can select the Kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

Instructions of how to setup Neuron Tensorflow environment and run the tutorial as a Jupyter notebook are available in the Tensorflow Quick Setup

9.5.3 Compile for Neuron

A trained model must be compiled to Inferentia target before it can be deployed on Inferentia instances. In this step we compile the Keras ResNet50 model and export it as a SavedModel which is an interchange format for TensorFlow models. At the end of compilation, the compiled SavedModel is saved in resnet50_neuron local directory:

[ ]:
```
import os
import time
import shutil
import tensorflow as tf
import tensorflow.neuron as tfn
import tensorflow.compat.v1.keras as keras
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras.applications.resnet50 import preprocess_input

# Create a workspace
WORKSPACE = './ws_resnet50'
os.makedirs(WORKSPACE, exist_ok=True)

# Prepare export directory (old one removed)
model_dir = os.path.join(WORKSPACE, 'resnet50')
compiled_model_dir = os.path.join(WORKSPACE, 'resnet50_neuron')
shutil.rmtree(model_dir, ignore_errors=True)
shutil.rmtree(compiled_model_dir, ignore_errors=True)

# Instantiate Keras ResNet50 model
keras.backend.set_learning_phase(0)
keras.backend.set_image_data_format('channels_last')

model = ResNet50(weights='imagenet')

# Export SavedModel
tf.saved_model.simple_save(
    session            = keras.backend.get_session(),
    export_dir         = model_dir,
    inputs             = {'input': model.inputs[0]},
```

(continues on next page)

(continued from previous page)

```
    outputs             = {'output': model.outputs[0]})

# Compile using Neuron
tfn.saved_model.compile(model_dir, compiled_model_dir)
```

[ ]:
```
!ls
```

9.5.4 Deploy on Inferentia

Using same instance to deploy the model. In case of different deployment instance, launch a deployment inf1 instance and copy compiled model to the deployment inf1 instance.

Download the example image, and install pillow module for inference on deployement instance

[ ]:
```
!curl -O https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/docs/images/
↪kitten_small.jpg
!pip install pillow  # Necessary for loading images
```

After downloading the example image, run the inference.

[ ]:
```
import os
import time
import numpy as np
import tensorflow as tf
from tensorflow.keras.preprocessing import image
from tensorflow.keras.applications import resnet50

tf.keras.backend.set_image_data_format('channels_last')

# Create input from image
img_sgl = image.load_img('kitten_small.jpg', target_size=(224, 224))
img_arr = image.img_to_array(img_sgl)
img_arr2 = np.expand_dims(img_arr, axis=0)
img_arr3 = resnet50.preprocess_input(img_arr2)

# Load model
COMPILED_MODEL_DIR = './ws_resnet50/resnet50_neuron/'
predictor_inferentia = tf.contrib.predictor.from_saved_model(COMPILED_MODEL_DIR)

# Run inference
model_feed_dict={'input': img_arr3}
infa_rslts = predictor_inferentia(model_feed_dict);

# Display results
print(resnet50.decode_predictions(infa_rslts["output"], top=5)[0])

# Sample output will look like below:
#[('n02123045', 'tabby', 0.68817204), ('n02127052', 'lynx', 0.12701613), ('n02123159', 'tiger_
↪cat', 0.08736559), ('n02124075', 'Egyptian_cat', 0.063844085), ('n02128757', 'snow_leopard',␣
↪0.009240591)]
```

9.6 Working with YOLO v4 using AWS Neuron SDK

The /src/examples/tensorflow/yolo_v4_demo/evaluate.ipynb notebook contains an example on how to take an open source YOLO v4 models, and run it on AWS Inferentia.

9.6.1 Optimizing image pre-processing and post-processing for object detection models

End-to-end object detection pipelines usually contain image pre-post-processing operators that cannot run efficiently on Inferentia. DecodeJPEG and NonMaxSuppression are typical examples. In practice, we may simply place these operators on CPU using the AWS Neuron machine learning framework integration. However, Inferentia is such a high performance machine learning accelerator that, once the model successfully compiles and runs, these simple pre-post-processing operators can become the new performance bottleneck! In this tutorial, we explain some commonly used tensorflow techniques for optimizing the performance of these pre-post-processing operators so that we can fully unleash the potential of Inferentia.

1. Write JPEG decoding and image shifting/scaling as tensorflow operators.

In `yolo_v4_coco_saved_model.py`, you may find the following code snippet.

```
import tensorflow as tf
...

def YOLOv4(...
    ...
    x, image_shape = layers.Lambda(lambda t: preprocessor(t, input_shape))(inputs)

    # cspdarknet53
    x = conv2d_unit(x, i32, 3, strides=1, padding='same')
...

def decode_jpeg_resize(input_tensor, image_size):
    tensor = tf.image.decode_png(input_tensor, channels=3)
    shape = tf.shape(tensor)
    tensor = tf.cast(tensor, tf.float32)
    tensor = tf.image.resize(tensor, image_size)
    tensor /= 255.0
    return tf.cast(tensor, tf.float16), shape

def preprocessor(input_tensor, image_size):
    with tf.name_scope('Preprocessor'):
        tensor = tf.map_fn(
            partial(decode_jpeg_resize, image_size=image_size), input_tensor,
            dtype=(tf.float16, tf.int32), back_prop=False, parallel_iterations=16)
    return tensor
```

Comparing with the implementation in the original repo, our difference is the use of `tf.image.decode_png` and `tf.image.resize`, along with a small number of scaling/casting operators. After this modification, the generated

tensorflow SavedModel now takes JPEG image raw bytes as input, instead of a float32 array representing the image. When the image resolution is 608x608, this technique effectively reduces the input image size from 4.4 MB to the size of a typical JPEG image, which can be as little as hundreds of KB. When the tensorflow SavedModel is deployed through tensorflow/serving, this technique can very effectively reduce the gRPC transfer overhead of input images.

2. Replace non-max suppression (NMS) operations by `tf.image.combined_non_max_suppression`.

Another difference of our implementation is the treatment of non-max suppression, a commmonly used operation for removing redundant bounding boxes that overlap with other boxes. In an object detection scenario represented by the COCO dataset where the number of output classes is large, the hand-fused `tf.image.combined_non_max_suppression <https://www.tensorflow.org/versions/r1.15/api_docs/python/tf/image/combined_non_max_suppression>`__ operator can parallelize multi-class NMS on CPU in a very efficient manner. With proper use of this operator, the bounding box post-processing step has a less chance of becoming the performance bottleneck in the end-to-end object detection pipeline.

The following sample code (from `yolo_v4_coco_saved_model.py`) demonstrates our method of writing the bounding box post-processing step using efficient tensorflow operations.

```
...
    def filter_boxes(outputs):
        boxes_l, boxes_m, boxes_s, box_scores_l, box_scores_m, box_scores_s, image_shape␣
↪= outputs
        boxes_l, box_scores_l = filter_boxes_one_size(boxes_l, box_scores_l)
        boxes_m, box_scores_m = filter_boxes_one_size(boxes_m, box_scores_m)
        boxes_s, box_scores_s = filter_boxes_one_size(boxes_s, box_scores_s)
        boxes = tf.concat([boxes_l, boxes_m, boxes_s], axis=0)
        box_scores = tf.concat([box_scores_l, box_scores_m, box_scores_s], axis=0)
        image_shape_wh = image_shape[1::-1]
        image_shape_whwh = tf.concat([image_shape_wh, image_shape_wh], axis=-1)
        image_shape_whwh = tf.cast(image_shape_whwh, tf.float32)
        boxes *= image_shape_whwh
        boxes = tf.expand_dims(boxes, 0)
        box_scores = tf.expand_dims(box_scores, 0)
        boxes = tf.expand_dims(boxes, 2)
        nms_boxes, nms_scores, nms_classes, valid_detections = tf.image.combined_non_max_
↪suppression(
            boxes,
            box_scores,
            max_output_size_per_class=nms_top_k,
            max_total_size=nms_top_k,
            iou_threshold=nms_thresh,
            score_threshold=conf_thresh,
            pad_per_class=False,
            clip_boxes=False,
            name='CombinedNonMaxSuppression',
        )
        return nms_boxes[0], nms_scores[0], nms_classes[0]

    def filter_boxes_one_size(boxes, box_scores):
        box_class_scores = tf.reduce_max(box_scores, axis=-1)
        keep = box_class_scores > conf_thresh
        boxes = boxes[keep]
        box_scores = box_scores[keep]
        return boxes, box_scores
```

(continues on next page)

(continued from previous page)

```
    def batch_yolo_out(outputs):
        with tf.name_scope('yolo_out'):
            b_output_lr, b_output_mr, b_output_sr, b_image_shape = outputs

9.7 Evaluate YOLO v3 on Inferentia

9.7.1 Note: this tutorial runs on tensorflow-neuron 1.x only

9.7.2 Introduction

This tutorial walks through compiling and evaluating YOLO v3 model on Inferentia using the AWS Neuron SDK.

In this tutorial we provide two main sections:

1. Download Dataset and Generate Pretrained SavedModel
2. Compile the YOLO v3 model.
3. Deploy the same compiled model.

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the Tensorflow Installation Guide. You can select the Kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

Instructions of how to setup Neuron Tensorflow environment and run the tutorial as a Jupyter notebook are available in the Tutorial main page Tensorflow-YOLO_v3 Tutorial

9.7.3 Prerequisites

This demo requires the following pip packages:

`pillow matplotlib pycocotools`

[ ]:
```
import sys
!{sys.executable} -m pip install pillow matplotlib pycocotools==2.0.2 --force --extra-
↪index-url=https://pip.repos.neuron.amazonaws.com
```

9.7.4 Part 1: Download Dataset and Generate Pretrained SavedModel

Download COCO 2017 validation dataset

We start by downloading the COCO validation dataset, which we will use to validate our model. The COCO 2017 dataset is widely used for object-detection, segmentation and image captioning.

[ ]:
```
!curl -LO http://images.cocodataset.org/zips/val2017.zip
!curl -LO http://images.cocodataset.org/annotations/annotations_trainval2017.zip
!unzip -q val2017.zip
!unzip annotations_trainval2017.zip
```

[ ]:
```
!ls
```

9.7.5 Generate YOLO v3 tensorflow SavedModel (pretrained on COCO 2017 dataset)

Script yolo_v3_coco_saved_model.py will generate a tensorflow SavedModel using pretrained weights from https://github.com/YunYang1994/tensorflow-yolov3/releases/download/v1.0/yolov3_coco.tar.gz.

[ ]:
```
%run yolo_v3_coco_saved_model.py ./yolo_v3_coco_saved_model
```

This tensorflow SavedModel can be loaded as a tensorflow predictor. When a JPEG format image is provided as input, the output result of the tensorflow predictor contains information for drawing bounding boxes and classification results.

[ ]:
```
import json
import tensorflow as tf
from PIL import Image
import matplotlib.pyplot as plt
import matplotlib.patches as patches

# launch predictor and run inference on an arbitrary image in the validation dataset
yolo_pred_cpu = tf.contrib.predictor.from_saved_model('./yolo_v3_coco_saved_model')
image_path = './val2017/000000581781.jpg'
with open(image_path, 'rb') as f:
    feeds = {'image': [f.read()]}
results = yolo_pred_cpu(feeds)

# load annotations to decode classification result
with open('./annotations/instances_val2017.json') as f:
    annotate_json = json.load(f)
```

(continues on next page)

(continued from previous page)

```
label_info = {idx+1: cat['name'] for idx, cat in enumerate(annotate_json['categories'])}

# draw picture and bounding boxes
fig, ax = plt.subplots(figsize=(10, 10))
ax.imshow(Image.open(image_path).convert('RGB'))
wanted = results['scores'][0] > 0.1
for xyxy, label_no_bg in zip(results['boxes'][0][wanted], results['classes'][0][wanted]):
    xywh = xyxy[0], xyxy[1], xyxy[2] - xyxy[0], xyxy[3] - xyxy[1]
    rect = patches.Rectangle((xywh[0], xywh[1]), xywh[2], xywh[3], linewidth=1,␣
↪edgecolor='g', facecolor='none')
    ax.add_patch(rect)
    rx, ry = rect.get_xy()
    rx = rx + rect.get_width() / 2.0
    ax.annotate(label_info[label_no_bg + 1], (rx, ry), color='w', backgroundcolor='g',␣
↪fontsize=10,
                ha='center', va='center', bbox=dict(boxstyle='square,pad=0.01', fc='g',␣
↪ec='none', alpha=0.5))
plt.show()
```

9.7.6 Part 2: Compile the Pretrained SavedModel for Neuron

We make use of the Python compilation API `tfn.saved_model.compile` that is available in `tensorflow-neuron<2`. For the purpose of reducing Neuron runtime overhead, it is necessary to make use of arguments `no_fuse_ops` and `minimum_segment_size`. Compiled model is saved in ./yolo_v3_coco_saved_model_neuron.

[ ]:
```
import shutil
import tensorflow as tf
import tensorflow.neuron as tfn

def no_fuse_condition(op):
    return op.name.startswith('Preprocessor') or op.name.startswith('Postprocessor')

with tf.Session(graph=tf.Graph()) as sess:
    tf.saved_model.loader.load(sess, ['serve'], './yolo_v3_coco_saved_model')
    no_fuse_ops = [op.name for op in sess.graph.get_operations() if no_fuse_
↪condition(op)]
shutil.rmtree('./yolo_v3_coco_saved_model_neuron', ignore_errors=True)
result = tfn.saved_model.compile(
    './yolo_v3_coco_saved_model', './yolo_v3_coco_saved_model_neuron',
    # to enforce trivial compilable subgraphs to run on CPU
    no_fuse_ops=no_fuse_ops,
    minimum_segment_size=100,
    batch_size=2,
    dynamic_batch_size=True,
)
print(result)
```

9.7.7 Deploy the model on Inferentia

9.7.8 Part 3:Evaluate Model Quality after Compilation

Define evaluation functions

We first define some handy helper functions for running evaluation on the COCO 2017 dataset.

[ ]:
```
import os
import json
import time
import numpy as np
import tensorflow as tf
from pycocotools.coco import COCO
from pycocotools.cocoeval import COCOeval

def cocoapi_eval(jsonfile,
                 style,
                 coco_gt=None,
                 anno_file=None,
                 max_dets=(100, 300, 1000)):
    """
    Args:
        jsonfile: Evaluation json file, eg: bbox.json, mask.json.
        style: COCOeval style, can be `bbox` , `segm` and `proposal`.
        coco_gt: Whether to load COCOAPI through anno_file,
                 eg: coco_gt = COCO(anno_file)
        anno_file: COCO annotations file.
        max_dets: COCO evaluation maxDets.
    """
    assert coco_gt is not None or anno_file is not None

    if coco_gt is None:
        coco_gt = COCO(anno_file)
    print("Start evaluate...")
    coco_dt = coco_gt.loadRes(jsonfile)
    if style == 'proposal':
        coco_eval = COCOeval(coco_gt, coco_dt, 'bbox')
        coco_eval.params.useCats = 0
        coco_eval.params.maxDets = list(max_dets)
    else:
        coco_eval = COCOeval(coco_gt, coco_dt, style)
    coco_eval.evaluate()
    coco_eval.accumulate()
    coco_eval.summarize()
    return coco_eval.stats

def bbox_eval(anno_file, bbox_list):
    coco_gt = COCO(anno_file)

    outfile = 'bbox_detections.json'
```

(continues on next page)

(continued from previous page)

```
    print('Generating json file...')
    with open(outfile, 'w') as f:
        json.dump(bbox_list, f)

    map_stats = cocoapi_eval(outfile, 'bbox', coco_gt=coco_gt)
    return map_stats

def get_image_as_bytes(images, eval_pre_path):
    batch_im_id_list = []
    batch_im_name_list = []
    batch_img_bytes_list = []
    n = len(images)
    batch_im_id = []
    batch_im_name = []
    batch_img_bytes = []
    for i, im in enumerate(images):
        im_id = im['id']
        file_name = im['file_name']
        if i % eval_batch_size == 0 and i != 0:
            batch_im_id_list.append(batch_im_id)
            batch_im_name_list.append(batch_im_name)
            batch_img_bytes_list.append(batch_img_bytes)
            batch_im_id = []
            batch_im_name = []
            batch_img_bytes = []
        batch_im_id.append(im_id)
        batch_im_name.append(file_name)

        with open(os.path.join(eval_pre_path, file_name), 'rb') as f:
            batch_img_bytes.append(f.read())
    return batch_im_id_list, batch_im_name_list, batch_img_bytes_list

def analyze_bbox(results, batch_im_id, _clsid2catid):
    bbox_list = []
    k = 0
    for boxes, scores, classes in zip(results['boxes'], results['scores'], results[
↪'classes']):
        if boxes is not None:
            im_id = batch_im_id[k]
            n = len(boxes)
            for p in range(n):
                clsid = classes[p]
                score = scores[p]
                xmin, ymin, xmax, ymax = boxes[p]
                catid = (_clsid2catid[int(clsid)])
                w = xmax - xmin + 1
                h = ymax - ymin + 1

                bbox = [xmin, ymin, w, h]
                # Round to the nearest 10th to avoid huge file sizes, as COCO suggests
```

(continues on next page)

(continued from previous page)

```
                bbox = [round(float(x) * 10) / 10 for x in bbox]
                bbox_res = {
                    'image_id': im_id,
                    'category_id': catid,
                    'bbox': bbox,
                    'score': float(score),
                }
                bbox_list.append(bbox_res)
        k += 1
    return bbox_list
```

Here is the actual evaluation loop. To fully utilize all four cores on one Inferentia, the optimal setup is to run multi-threaded inference using a `ThreadPoolExecutor`. The following cell is a multi-threaded adaptation of the evaluation routine at https://github.com/miemie2013/Keras-YOLOv4/blob/910c4c6f7265f5828fceed0f784496a0b46516bf/tools/cocotools.py#L97.

[ ]:
```
from concurrent import futures

def evaluate(yolo_predictor, images, eval_pre_path, anno_file, eval_batch_size, _
↪clsid2catid):
    batch_im_id_list, batch_im_name_list, batch_img_bytes_list = get_image_as_
↪bytes(images, eval_pre_path)

    # warm up

9.8 Running SSD300 with AWS Neuron

*Update 11/16: The model checkpoint link*https://api.ngc.nvidia.com/v2/models/nvidia/ssdpyt_fp32/versions/1/files/nvidia_ssdpyt_fp32_20190225.pt*is currently broken and the AWS Neuron team is working on providing an alternative source.*

This demo shows a Neuron compatible SSD300 implementation that is functionally equivalent to open source SSD300 model. This demo uses TensorFlow-Neuron, PyTorch SSD300 model and checkpoint (https://pytorch.org/hub/nvidia_deeplearningexamples_ssd/) and also shows the performance achieved by the Inf1 instance.

9.8.1 Table of Contents

1. Launch EC2 instance and update AWS Neuron SDK software
2. Generating Neuron compatible SSD300 TensorFlow SavedModel
   - Convert open source PyTorch SSD300 model and checkpoint into Neuron compatible SSD300 TensorFlow SavedModel
3. Evaluate the generated SSD300 TensorFlow SavedModel for both accuracy and performance
   - Running threaded inference through the COCO 2017 validation dataset

9.8.2 Launch EC2 instances and update tensorflow-neuron and neuron-cc

For this demo, launch one inf1.xlarge EC2 instance. We recommend using the latest Ubuntu 18 Deep Learning AMI (DLAMI).

Please configure your ubuntu16/ubuntu18/yum repo following the steps in the *Install TensorFlow Neuron* in order to install `tensorflow-model-server-neuron`.

9.8.3 Generating Neuron compatible SSD300 TensorFlow SavedModel

First connect to your inf1.xlarge instance

Compile open source PyTorch SSD300 model and checkpoint into Neuron compatible SSD300 TensorFlow SavedModel

In the same directory ssd300_demo, run the following:

1. Create venv and install dependencies

```
sudo apt update
sudo apt install g++ python3-dev python3-venv unzip
sudo apt install tensorflow-model-server-neuron
python3 -m venv env
source ./env/bin/activate
pip install pip setuptools --upgrade
pip install -r ./requirements.txt --extra-index-url=https://pip.repos.neuron.amazonaws.
↪com
```

2. Clone NVIDIA's DeepLearningExamples repo that contains PyTorch SSD300.

```
git clone https://github.com/NVIDIA/DeepLearningExamples.git
cd DeepLearningExamples
git checkout a644350589f9abc91b203f73e686a50f5d6f3e96
cd ..
```

3. Download PyTorch SSD300 checkpoint file.

```
curl -LO https://api.ngc.nvidia.com/v2/models/nvidia/ssdpyt_fp32/versions/1/files/nvidia_
↪ssdpyt_fp32_20190225.pt
```

4. Download COCO 2017 validation set and annotations.

```
curl -LO http://images.cocodataset.org/zips/val2017.zip
unzip ./val2017.zip
curl -LO http://images.cocodataset.org/annotations/annotations_trainval2017.zip
unzip ./annotations_trainval2017.zip
```

5. Convert PyTorch SSD300 model and checkpoint into a Neuron-compatible TensorFlow SavedModel.

```
python ssd300_model.py --torch_checkpoint=./nvidia_ssdpyt_fp32_20190225.pt --output_
↪saved_model=./ssd300_tf_neuron/1
```

This converts PyTorch SSD300 model and checkpoint to a Neuron-compatible TensorFlow SavedModel using tensorflow-neuron and neuron-cc. The compilation output is stored in `./ssd300_tf_neuron`.

6. Launch the `tensorflow-model-server-neuron` gRPC server at default port 8500 in the background.

```
tensorflow_model_server_neuron --model_base_path=$(pwd)/ssd300_tf_neuron &
```

7. In client, evaluate the Neuron-compatible TensorFlow SavedModel for both accuracy and performance. Note that this client by default assumes a `tensorflow-model-server-neuron` listening at `localhost:8500`. On inf1.xlarge, the expected throughput is 100 images/second once the server is fully warmed up, and the expected mean average precision (mAP) is 0.253.

```
python ssd300_evaluation_client.py --val2017=./val2017 --instances_val2017_json=./
↪annotations/instances_val2017.json
```

8. After running the demo, please cleanup resources allocated in Neuron runtime by gracefully killing the `tensorflow_model_server_neuron` process, e. g.,

```
killall tensorflow_model_server_neuron
```

This document is relevant for: `Inf1`

9.9 Tensorflow ResNet 50 Optimization Tutorial

9.9.1 Note: this tutorial runs on tensorflow-neuron 1.x only

9.9.2 Introduction:

In this tutorial we provide three main sections:

- Take a Resnet 50 model and perform optimizations on it
- Compile the model with different batch sizes and Neuroncore Group sizes (read about Neuroncore Group sizes here: https://awsdocs-neuron.readthedocs-hosted.com/en/latest/neuron-guide/neuron-runtime/nrt-theory-of-operation.html#neuron-core-group)
- Run inference on our multiple compiled models to see which has the best throughput

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the Tensorflow Installation Guide. You can select the Kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

9.9.3 Install Dependencies

[ ]:
```
!pip install pillow requests # Necessary for loading images
!pip install 'tensorflow-neuron<2' --extra-index-url=https://pip.repos.neuron.amazonaws.
↪com
```

9.9.4 Compile

The following example shows how to compile a FP16 ResNet50 network using various batching parameters to find the optimal solution. On inf1.6xlarge, run through the following steps to get a optimized Resnet 50 model. First, extract Keras ResNet50 FP32 (resnet50_fp32_keras.pb will be generated):

[ ]:
```
import re
import argparse
import tensorflow as tf
import numpy as np

from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras.preprocessing import image
from tensorflow.keras.applications.resnet50 import preprocess_input, decode_predictions

from google.protobuf import text_format
import tensorflow.python.saved_model

# set Keras global configurations
tf.keras.backend.set_learning_phase(0)
tf.keras.backend.set_image_data_format('channels_last')

float_type = 'float32'
float_type2 = 'fp32'
tf.keras.backend.set_floatx(float_type)

# load pre-trained model using Keras
model_name = 'resnet50_%s_keras'%float_type2
model = ResNet50(weights='imagenet')

# various save files
frozen_file = model_name + '.pb'
opt_file = model_name + '_opt.pb'

# obtain parameters
model_input = model.input.name.replace(':0', '')
model_output = model.output.name.replace(':0', '')
batch, height, width, channels = model.input.shape

print ("model, frozen file, optimized file, input size, input node, output node,")
print ("%s, %s, %s, %dx%dx%d, %s, %s" %(model_name, frozen_file, opt_file, width,␣
↪height, channels, model_input, model_output) )

# obtain the TF session
sess = tf.compat.v1.keras.backend.get_session()
```

(continues on next page)

(continued from previous page)

```
# save checkpoint files for freeze_graph
ckpt_file = '/tmp/' + model_name + '/' + model_name + '.ckpt'
graph_file = '/tmp/' + model_name + '/' + model_name + '.pb'
tf.compat.v1.train.Saver().save(sess, ckpt_file)
tf.io.write_graph(sess.graph.as_graph_def(), logdir='.', name=graph_file, as_text=False)

print(model_output)
with tf.compat.v1.Session(graph=tf.Graph()) as sess:
      saver = tf.compat.v1.train.import_meta_graph(ckpt_file + '.meta')
      saver.restore(sess, ckpt_file)
      output_graph_def = tf.compat.v1.graph_util.convert_variables_to_constants(
          sess, tf.compat.v1.get_default_graph().as_graph_def(), [model_output])
      output_graph_def = tf.compat.v1.graph_util.remove_training_nodes(
          output_graph_def, protected_nodes=[model_output])
      with open(frozen_file, 'wb') as f:
          f.write(output_graph_def.SerializeToString())
```

Optimize the extracted Keras ResNet50 FP32 graph for inference before casting (resnet50_fp32_keras_opt.pb will be generated) with the following transformations to the graph:

- Remove Identity and CheckNumerics nodes
- Fold FusedBatchNorm constants into previous Conv2D weights
- Fold other constants
- Strip unused nodes
- Sort by execution order

[ ]:
```
import copy
import string

from google.protobuf import text_format

Run the compilation script to sweep through various batch sizes up to 5 and several NeuronCore Group sizes up to 16. The script calls the compilation script pb2sm_compile.py which tries to perform compilation. Some error messages are expected due to known issues (see Known Issues section in the tutorial). If you run all the configurations it will take about 45 minutes.

[ ]:
```
%%bash
#!/usr/bin/env bash

echo "" > full_sweep.log
echo "" > full_sweep_results.txt

results=()
for b in $(seq 1 5); do
    for i in 1 2 4 8 12 16; do
        python pb2sm_compile.py --batch_size=$b --neuroncore-pipeline-cores=$i | tee -a␣
↪full_sweep.log;
        results[$b]+=", "`tail -1 full_sweep.log`
    done
done

head="batch"
for i in 1 2 4 8 12 16; do
    head+=", nc${i}"
done
echo $head | tee -a full_sweep_results.txt
for b in $(seq 1 5); do
    echo $b${results[$b]} | tee -a full_sweep_results.txt
done
```

You should see some output like this:

5, 1, 1, 0, 0, 0, 0
```

9.9.5 Inference

Run inference over different batch sizes and Neuroncore groups to obtain throughput and latency results for ResNet50. To apply dynamic batching, the user batch size is set to 10x the compiled batch size, in order to keep input queue full and to amortize framework-to-Neuron overhead.

Note: The results are based on the Neuron v1.12.2 (Mar 4th 2021) release. These will continue improve as we increase Neuron performance.

[ ]:
```
!cd ~/aws-neuron-sdk/src/examples/tensorflow/keras_resnet50/
!echo "" > batch.log
!for i in $(seq 1 5); do python infer_resnet50_keras_loadtest.py --batch_size=$i --
↪neuroncore-pipeline-cores=1 | tee -a batch.log; done
!for i in $(seq 1 5); do python infer_resnet50_keras_loadtest.py --batch_size=$i --
↪neuroncore-pipeline-cores=2 | tee -a batch.log; done
!for i in $(seq 1 5); do python infer_resnet50_keras_loadtest.py --batch_size=$i --
↪neuroncore-pipeline-cores=4 | tee -a batch.log; done
!for i in $(seq 1 5); do python infer_resnet50_keras_loadtest.py --batch_size=$i --
↪neuroncore-pipeline-cores=8 | tee -a batch.log; done
!for i in $(seq 1 5); do python infer_resnet50_keras_loadtest.py --batch_size=$i --
↪neuroncore-pipeline-cores=12 | tee -a batch.log; done
!for i in $(seq 1 5); do python infer_resnet50_keras_loadtest.py --batch_size=$i --
↪neuroncore-pipeline-cores=16 | tee -a batch.log; done
```

The file batch.log now contains the results for each batch size. We can look at the throughput values to get an idea of which models are performing well. The output should look something like this:

The model best model configuration for throughput (if you run on an Inf1.6xlarge as suggested in the tutorial) is batch size 5 NeuronCore group size 2. Increasing batch size usually helps to increase throughput (up to a certain extent).

```
*** Compiled batch size 5, user batch size 10, num NeuronCores 2 (input shape: (10, 224,␣
↪224, 3), saved model dir: ./rn50_fp16_compiled_b5_nc2/1) ***

NUM THREADS:  16
NUM_LOOPS_PER_THREAD:  400
USER_BATCH_SIZE:  10
Throughput values collected:
[10680, 10700, 10660]

(rest of outputs removed)
```

9.9.6 Known Issues

Unable to compile with batch and num NeuronCores combination

For some combination of batch and number of NeuronCores setting, you may see an internal compiler error as below. Please see the sweep result above for Neuron 1/27/20 release. Furthermore, if using auto-casting to bfloat16 from FP32 network and batch size is larger than 1 would result in the same error.

```

Natural Language Processing (NLP) Tutorials

- Tensorflow 1.x - Running TensorFlow BERT-Large with AWS Neuron *[html]*
- Tensorflow 2.x - HuggingFace Pipelines distilBERT with Tensorflow2 Neuron *[html]* [notebook]

This document is relevant for: `Inf1`

9.10 Running TensorFlow BERT-Large with AWS Neuron

This example shows a Neuron compatible BERT-Large implementation that is functionally equivalent to open source BERT-Large model. This demo uses TensorFlow-Neuron, BERT-Large weights fine tuned for MRPC and also shows the performance achieved by the Inf1 instance. For users who want to use public BERT SavedModels please also follow the steps described *Using public BERT SavedModels*.

9.10.1 Launch EC2 instances

For this demo, launch two EC2 instances :

- a c5.4xlarge instance for compiling the BERT-Large Model and
- an inf1.xlarge instance for running inference

For both of these instances choose the latest Ubuntu 18 Deep Learning AMI (DLAMI).

9.10.2 Compiling Neuron compatible BERT-Large

First connect to a c5.4xlarge instance and update tensorflow-neuron and neuron-cc

Update compilation EC2 instance

Update to the latest neuron software by executing the instructions at *Install TensorFlow Neuron*.

Note: if your tensorflow-neuron version on the inference instance is lower than 1.15.0.1.0.1333.0, you will need to run this demo on inf1.2xlarge instead of inf1.xlarge.

Compile open source BERT-Large saved model using Neuron compatible BERT-Large implementation

Neuron software works with TensorFlow saved models. Users should bring their own BERT-Large saved model for this section. This demo will run inference for the MRPC task and the saved model should be fine tuned for MRPC. Users who need additional help to fine-tune the model for MRPC or to create a saved model can refer to *Appendix 1*.

In the same environment and directory bert_demo scripts, run the following :

```
git clone https://github.com/aws/aws-neuron-sdk
cd ~/aws-neuron-sdk/src/examples/tensorflow/bert_demo/
export BERT_LARGE_SAVED_MODEL="/path/to/user/bert-large/savedmodel"
python bert_model.py --input_saved_model $BERT_LARGE_SAVED_MODEL --output_saved_model ./
↪bert-saved-model-neuron --batch_size=6 --aggressive_optimizations
```

This compiles BERT-Large pointed to by $BERT_LARGE_SAVED_MODEL for an input size of 128 and batch size of 6. The compilation output is stored in bert-saved-model-neuron. Copy this to your Inf1 instance for inferencing.

The bert_model.py script encapsulates all the steps necessary for this process. For details on what is done by bert_model.py please refer to *Appendix 2*.

9.10.3 Running the inference demo

Connect to your inf1.xlarge instance and update tensorflow-neuron, aws-neuron-runtime and aws-neuron-tools.

Update inference EC2 instance

Update to the latest neuron software by executing the instructions at *Install TensorFlow Neuron*.

Launching the BERT-Large demo server

Copy the compiled model (bert-saved-model-neuron) from your c5.4xlarge to your inf1.xlarge instance. Place the model in the same directory as the bert_demo scripts. Then from the same conda environment launch the BERT-Large demo server :

```
cd ~/aws-neuron-sdk/src/examples/tensorflow/bert_demo/
python bert_server.py --dir bert-saved-model-neuron --batch 6 --parallel 4
```

This loads 4 BERT-Large models, one into each of the 4 NeuronCores found in an inf1.xlarge instance. For each of the 4 models, the BERT-Large demo server opportunistically stitches together asynchronous requests into batch 6 requests. When there are insufficient pending requests, the server creates dummy requests for batching.

Wait for the bert_server to finish loading the BERT-Large models to Inferentia memory. When it is ready to accept requests it will print the inferences per second once every second. This reflects the number of real inferences only. Dummy requests created for batching are not credited to inferentia performance. Once the inferences are done you can send a keyboard interrupt to print out the average throughput of your run.

Sending requests to server from multiple clients

Wait until the bert demo server is ready to accept requests. Then on the same inf1.xlarge instance, launch a separate linux terminal. From the bert_demo directory execute the following commands :

```
source activate aws_neuron_tensorflow_p36
cd ~/aws-neuron-sdk/src/examples/tensorflow/bert_demo/
for i in {1..96}; do python bert_client.py --cycle 128 & done
```

This spins up 96 clients, each of which sends 128 inference requests.

Printing latency metrics

After all your requests have been sent to your server you can run the following command:

```
python latency_printer.py
```

9.10.4 Using public BERT SavedModels

We are now providing a compilation script that has better compatibility with various flavors of BERT SavedModels generated from https://github.com/google-research/bert. Here are the current limitations:

1. You did not change modeling.py
2. BERT SavedModel is generated using `estimator.export_saved_model`
3. BERT SavedModel uses fixed sequence length 128 (you may check by `saved_model_cli show --dir /path/to/user/bert/savedmodel --all`)
4. `neuron-cc` version is at least 1.0.12000.0
5. `aws-neuron-runtime` version is at least 1.0.7000.0
6. The `--batch_size` argument specified in this script is at most 4

Example usage is shown below:

```
export BERT_LARGE_SAVED_MODEL="/path/to/user/bert-large/savedmodel"
cd ~/aws-neuron-sdk/src/examples/tensorflow/bert_demo/
python bert_no_model.py --input_saved_model $BERT_LARGE_SAVED_MODEL --output_saved_model␣
↪./bert-saved-model-neuron --batch_size=1
```

9.10.5 Appendix 1

Users who need help finetuning BERT-Large for MRPC and creating a saved model may follow the instructions here.

Connect to the c5.4xlarge compilation EC2 instance you started above and download these three items :

1. clone this github repo.
2. download GLUE data as described here. Do not run the finetuning command.
3. download a desired pre-trained BERT-Large checkpoint from here. This is the model we will fine tune.

Next edit run_classifier.py in the cloned bert repo to apply the patch described in the following git diff.

```
diff --git a/run_classifier.py b/run_classifier.py
index 817b147..c9426bc 100644
--- a/run_classifier.py
+++ b/run_classifier.py
@@ -955,6 +955,18 @@ def main(_):
         drop_remainder=predict_drop_remainder)

     result = estimator.predict(input_fn=predict_input_fn)

     output_predict_file = os.path.join(FLAGS.output_dir, "test_results.tsv")
     with tf.gfile.GFile(output_predict_file, "w") as writer:
```

NOTE : Users who are interested may refer to this link for additional background information on the patch but it is not necessary for running this demo.

Then from the bert_demo directory run the following :

```
source activate aws_neuron_tensorflow_p36
cd ~/aws-neuron-sdk/src/examples/tensorflow/bert_demo/
export BERT_REPO_DIR="/path/to/cloned/bert/repo/directory"
export GLUE_DIR="/path/to/glue/data/directory"
export BERT_BASE_DIR="/path/to/pre-trained/bert-large/checkpoint/directory"
./tune_save.sh
```

The a saved model will be created in $BERT_REPO_DIR/bert-saved-model/*random_number*/. Where, *random_number* is a random number generated for every run. Use this saved model to continue with the rest of the demo.

9.10.6 Appendix 2

For all BERT variants, we currently need to augment the standard Neuron compilation process for performance tuning. In the future, we intend to automate this tuning process. This would allow users to use the standard Neuron compilation process, which requires only a one line change in user source code. The standard compilation process is described *Running Neuron Apache MXNet (Incubating) ResNet50 on Inferentia*.

The augmented Neuron compilation process is encapsulated by the bert_model.py script, which performs the following things :

1. Define a Neuron compatible implementation of BERT-Large. For inference, this is functionally equivalent to the open source BERT-Large. The changes needed to create a Neuron compatible BERT-Large implementation is described in *Appendix 3*.
2. Extract BERT-Large weights from the open source saved model pointed to by –input_saved_model and associates it with the Neuron compatible model
3. Invoke TensorFlow-Neuron to compile the Neuron compatible model for Inferentia using the newly associated weights
4. Finally, the compiled model is saved into the location given by –output_saved_model

9.10.7 Appendix 3

The Neuron compatible implementation of BERT-Large is functionally equivalent to the open source version when used for inference. However, the detailed implementation does differ and here are the list of changes :

1. Data Type Casting : If the original BERT-Large an FP32 model, bert_model.py contains manually defined cast operators to enable mixed-precision. FP16 is used for multi-head attention and fully-connected layers, and fp32 everywhere else. This will be automated in a future release.
2. Remove Unused Operators: A model typically contains training operators that are not used in inference, including a subset of the reshape operators. Those operators do not affect inference functionality and have been removed.
3. Reimplementation of Selected Operators : A number of operators (mainly mask operators), has been reimplemented to bypass a known compiler issue. This will be fixed in a planned future release.
4. Manually Partition Embedding Ops to CPU : The embedding portion of BERT-Large has been partitioned manually to a subgraph that is executed on the host CPU, without noticable performance impact. In near future, we plan to implement this through compiler auto-partitioning without the need for user intervention.

This document is relevant for: `Inf1`

9.11 Compiling and Deploying Pretrained HuggingFace Pipelines distilBERT with Tensorflow2 Neuron

9.11.1 Introduction

In this tutorial you will compile and deploy distilBERT version of HuggingFace Transformers BERT for Inferentia. The full list of HuggingFace's pretrained BERT models can be found in the BERT section on this page https://huggingface.co/transformers/pretrained_models.html. you can also read about HuggingFace's pipeline feature here: https://huggingface.co/transformers/main_classes/pipelines.html

This Jupyter notebook should be run on an instance which is inf1.6xlarge or larger, but in real life scenario the compilation should be done on a compute instance and the deployment on inf1 instance to save costs.

9.11.2 Setting up your environment:

To run this tutorial, please make sure you deactivate any existing TensorFlow conda environments you already using. Install TensorFlow 2.x by following the instructions at TensorFlow Tutorial Setup Guide.

After following the Setup Guide, you need to change your kernel to `Python (Neuron TensorFlow 2)` by clicking Kerenel->Change Kernel->`Python (Neuron TensorFlow 2)`

Now you can install TensorFlow Neuron 2.x, HuggingFace transformers, and HuggingFace datasets dependencies here.

[ ]:
```
!pip install --upgrade "transformers==4.1.0"
!pip install ipywidgets
```

[ ]:
```
from transformers import pipeline
import tensorflow as tf
import tensorflow.neuron as tfn
```

9.11.3 Compile the model into an AWS Neuron Optimized Model

[ ]:
```
#Create the huggingface pipeline for sentiment analysis
#this model tries to determine of the input text has a positive
#or a negative sentiment.
model_name = 'distilbert-base-uncased-finetuned-sst-2-english'

pipe = pipeline('sentiment-analysis', model=model_name, framework='tf')

#pipelines are extremely easy to use as they do all the tokenization,
#inference and output interpretation for you.
pipe(['I love pipelines, they are very easy to use!', 'this string makes it batch size␣
↪two'])
```

As yo've seen above, Huggingface's pipline feature is a great wrapper for running inference on their models. It takes care of the tokenization of the string inputs. Then feeds that tokenized input to the model. Finally it interprets the outputs of the model and formats them in a way that is very human readable. Our goal will be to compile the underlying model inside the pipeline as well as make some edits to the tokenizer. The reason you need to edit the tokenizer is to make sure that you have a standard sequence length (in this case 128) as neuron only accepts static input shapes.

[ ]:
```
neuron_pipe = pipeline('sentiment-analysis', model=model_name, framework='tf')

#the first step is to modify the underlying tokenizer to create a static
#input shape as inferentia does not work with dynamic input shapes
original_tokenizer = pipe.tokenizer

#you intercept the function call to the original tokenizer
#and inject our own code to modify the arguments
def wrapper_function(*args, **kwargs):
    kwargs['padding'] = 'max_length'
    #this is the key line here to set a static input shape
    #so that all inputs are set to a len of 128
    kwargs['max_length'] = 128
    kwargs['truncation'] = True
```

(continues on next page)

(continued from previous page)

```
    kwargs['return_tensors'] = 'tf'
    return original_tokenizer(*args, **kwargs)

#insert our wrapper function as the new tokenizer as well
#as reinserting back some attribute information that was lost
#when you replaced the original tokenizer with our wrapper function
neuron_pipe.tokenizer = wrapper_function
neuron_pipe.tokenizer.decode = original_tokenizer.decode
neuron_pipe.tokenizer.mask_token_id = original_tokenizer.mask_token_id
neuron_pipe.tokenizer.pad_token_id = original_tokenizer.pad_token_id
neuron_pipe.tokenizer.convert_ids_to_tokens = original_tokenizer.convert_ids_to_tokens

#Our example data!
string_inputs = [
    'I love to eat pizza!',
    'I am sorry. I really want to like it, but I just can not stand sushi.',
    'I really do not want to type out 128 strings to create batch 128 data.',
    'Ah! Multiplying this list by 32 would be a great solution!',
]
string_inputs = string_inputs * 32

example_inputs = neuron_pipe.tokenizer(string_inputs)
#compile the model by calling tfn.trace by passing in the underlying model
#and the example inputs generated by our updated tokenizer
neuron_model = tfn.trace(pipe.model, example_inputs)

#now you can insert the neuron_model and replace the cpu model
#so now you have a huggingface pipeline that uses and underlying neuron model!
neuron_pipe.model = neuron_model
neuron_pipe.model.config = pipe.model.config
```

9.11.4 Why use batch size 128?

You'll notice that in the above example we passed a two tensors of shape 128 (the batch size) x 128 (the sequence length) in this function call `tfn.trace(pipe.model, example_inputs)`. The example_inputs argument is important to `tfn.trace` because it tells the neuron model what to expect (remember that a neuron model needs static input shapes, so example_inputs defines that static input shape). A smaller batch size would also compile, but a large batch size ensures that the neuron hardware will be fed enough data to be as performant as possible.

9.11.5 What if my model isn't a Huggingface pipeline?

Not to worry! There is no requirement that your model needs to be Huggingface pipeline compatible. The Huggingface pipeline is just a wrapper for an underlying TensorFlow model (in our case `pipe.model`). As long as you have a TensorFlow 2.x model you can compile it on neuron by calling `tfn.trace(your_model, example_inputs)`. The processing the input and output to your own model is up to you! Take a look at the example below to see what happens when we call the model without the Huggingface pipeline wrapper as opposed to with it.

[ ]:
```
#directly call the model
print(neuron_model(example_inputs))
```

(continues on next page)

(continued from previous page)

```
#with the model inserted to the wrapper
print(neuron_pipe(string_inputs))

#Look at the difference between string_inputs
#and example_inputs

print(example_inputs)
print(string_inputs)
```

9.11.6 Save your neuron model to disk and avoid recompilation.

To avoid recompiling the model before every deployment, you can save the neuron model by calling `model_neuron.save(model_dir)`. This `save` method prefers to work on a flat input/output lists and does not work on dictionary input/output - which is what the Huggingface distilBERT expects as input. You can work around this by writing a simple wrapper that takes in an input list instead of a dictionary, compile the wrapped model and save it for later use.

[ ]:
```
class TFBertForSequenceClassificationFlatIO(tf.keras.Model):
    def __init__(self, model):
        super().__init__()
        self.model = model
    def call(self, inputs):
        input_ids, attention_mask = inputs
        output = self.model({'input_ids': input_ids, 'attention_mask': attention_mask})
        return output['logits']

#wrap the original model from HuggingFace, now our model accepts a list as input
model_wrapped = TFBertForSequenceClassificationFlatIO(pipe.model)
#turn the dictionary input into list input
example_inputs_list = [example_inputs['input_ids'], example_inputs['attention_mask']]

#compile the wrapped model and save it to disk
model_wrapped_traced = tfn.trace(model_wrapped, example_inputs_list)
model_wrapped_traced.save('./distilbert_b128')
```

[ ]:
```
!ls #you should now be able to see the model saved as the folder distilbert_b128
```

9.11.7 Load the model from disk

Now you can reload the model by calling `tf.keras.models.load_model(str : model_directory)`. This model is already compiled and could run inference on neuron, but if you want it to work with our Huggingface pipeline, you have to wrap it again to accept dictionary input.

[ ]:
```
class TFBertForSequenceClassificationDictIO(tf.keras.Model):
    def __init__(self, model_wrapped):
        super().__init__()
        self.model_wrapped = model_wrapped
        self.aws_neuron_function = model_wrapped.aws_neuron_function
    def call(self, inputs):
        input_ids = inputs['input_ids']
```

(continues on next page)

(continued from previous page)

```
        attention_mask = inputs['attention_mask']
        logits = self.model_wrapped([input_ids, attention_mask])
        return [logits]

reloaded_model = tf.keras.models.load_model('./distilbert_b128')
rewrapped_model = TFBertForSequenceClassificationDictIO(model_wrapped_traced)

#now you can reinsert our reloaded model back into our pipeline
neuron_pipe.model = rewrapped_model
neuron_pipe.model.config = pipe.model.config
```

9.11.8 Benchmarking the neuron model

Now you can do some simple benchmarking of the neuron model. If you are running this tutorial on a inf1.6xlarge, as suggested, you must tell neuron to use all 16 Neuron Cores to get maximum throughput. By default, TensorFlow Neuron will use only one Inferentia chip, which has 4 Neuron Cores. An inf1.6xlarge has 4 Inferentia chips. To tell Neuron to run on all available cores, you can set the environment variable `NEURONCORE_GROUP_SIZES` or launch multiple processes that query the same model. To read more about this refer to the Neuron Core groups section of our documentation. Use a warmup inference on the neuron model before benchmarking, as the first inference call also loads the model onto inferentia.

[ ]:
```
import warnings

warnings.warn("NEURONCORE_GROUP_SIZES is being deprecated, if your application is using␣
↪NEURONCORE_GROUP_SIZES please \
see https://awsdocs-neuron.readthedocs-hosted.com/en/latest/release-notes/deprecation.
↪html#announcing-end-of-support-for-neuroncore-group-sizes \
for more details.", DeprecationWarning)
%env NEURONCORE_GROUP_SIZES='16x1'

import time

#warmup inf
neuron_pipe(string_inputs)
#benchmark batch 128 neuron model
neuron_b128_times = []
for i in range(1000):
    start = time.time()
    outputs = neuron_pipe(string_inputs)
    end = time.time()
    neuron_b128_times.append(end - start)

neuron_b128_times = sorted(neuron_b128_times)

print(f"Average throughput for batch 128 neuron model is {128/(sum(neuron_b128_times)/
↪len(neuron_b128_times))} sentences/s.")
print(f"Peak throughput for batch 128 neuron model is {128/min(neuron_b128_times)}␣
↪sentences/s.")
print()
```

(continues on next page)

(continued from previous page)

```
print(f"50th percentile latency for batch 128 neuron model is {neuron_b128_
↪times[int(1000*.5)] * 1000} ms.")
print(f"90th percentile latency for batch 128 neuron model is {neuron_b128_
↪times[int(1000*.9)] * 1000} ms.")
print(f"95th percentile latency for bacth 128 neuron model is {neuron_b128_
↪times[int(1000*.95)] * 1000} ms.")
print(f"99th percentile latency for batch 128 neuron model is {neuron_b128_
↪times[int(1000*.99)] * 1000} ms.")
print()
```

[ ]:

```
```

Utilizing Neuron Capabilities Tutorials

- Tensorflow 1.x - Using NEURON_RT_VISIBLE_CORES with TensorFlow Serving *[html]*

This document is relevant for: `Inf1`

9.12 Using NEURON_RT_VISIBLE_CORES with TensorFlow Serving

TensorFlow serving allows customers to scale-up inference workloads across a network. TensorFlow Neuron Serving uses the same API as normal TensorFlow Serving with two differences: (a) the saved model must be compiled for Inferentia and (b) the entry point is a different binary named `tensorflow_model_server_neuron`. The binary is found at `/usr/local/bin/tensorflow_model_server_neuron` and is pre-installed in the DLAMI or installed with APT/YUM tensorflow-model-server-neuron package.

9.12.1 Install TensorFlow Model Server and Serving API

Follow the steps in the *Install TensorFlow Neuron*.

Then ensure you install using either apt-get or yum. If using TF 1.x, install the appropriate version (see above).:

```
sudo apt-get install tensorflow-model-server-neuron
```

or

```
sudo yum install tensorflow-model-server-neuron
```

Also, you would need TensorFlow Serving API (use –no-deps to prevent installation of regular tensorflow). Depending on the version of Tensorflow you wish to use:

For Tensorflow 1.x:

```
pip install --no-deps tensorflow_serving_api==1.15
```

For Tensorflow 2.x:

```
pip install --no-deps tensorflow_serving_api
```

For the example image preprocessing using Keras preprocessing, the Python Imaging Library Pillow is required:

```
pip install pillow
```

To workaround h5py issue https://github.com/aws/aws-neuron-sdk/issues/220:

```
pip install "h5py<3.0.0"
```

9.12.2 Export and Compile Saved Model

The following example shows graph construction followed by the addition of Neuron compilation step before exporting to saved model.

For Tensorflow 1.x:

```
import tensorflow as tf
import tensorflow.neuron

tf.keras.backend.set_learning_phase(0)
tf.keras.backend.set_image_data_format('channels_last')
model = tf.keras.applications.ResNet50(weights='imagenet')
sess = tf.keras.backend.get_session()
inputs = {'input': model.inputs[0]}
outputs = {'output': model.outputs[0]}

# save the model using tf.saved_model.simple_save
modeldir = "./resnet50/1"
tf.saved_model.simple_save(sess, modeldir, inputs, outputs)

# compile the model for Inferentia
neuron_modeldir = "./resnet50_inf1/1"
tf.neuron.saved_model.compile(modeldir, neuron_modeldir, batch_size=1)
```

For Tensorflow 2.x:

```
import tensorflow as tf
import tensorflow.neuron as tfn
import numpy as np

tf.keras.backend.set_learning_phase(0)
tf.keras.backend.set_image_data_format('channels_last')
image_sizes = [224, 224]
model = tf.keras.applications.ResNet50(weights='imagenet')
example_inputs = tf.random.uniform([1, *image_sizes, 3], dtype=tf.float32)

model_neuron = tfn.trace(model, example_inputs)
tf.keras.models.save_model(model_neuron, './resnet50_inf1/1')
```

9.12.3 Serving Saved Model

User can now serve the saved model with the tensorflow_model_server_neuron binary. To utilize multiple NeuronCores, it is recommended to launch multiple tensorflow model servers that listen to the same gRPC port:

```
export NEURON_RT_VISIBLE_CORES=0  # important to set this environment variable before␣
↪launching model servers
tensorflow_model_server_neuron --model_name=resnet50_inf1 \
     --model_base_path=$(pwd)/resnet50_inf1/ --port=8500

#then to run another server on a different neuron core open another
#window and run this, except this time set NEURON_RT_VISIBLE_CORES=1
#you can keep doing this up to the number of Neuron Cores on your machine

export NEURON_RT_VISIBLE_CORES=1
tensorflow_model_server_neuron --model_name=resnet50_inf1 \
     --model_base_path=$(pwd)/resnet50_inf1/ --port=8500
```

The compiled model is staged in Inferentia DRAM by the server to prepare for inference.

9.12.4 Generate inference requests to the model server

Now run inferences via GRPC as shown in the following sample client code:

For Tensorflow 1.x:

```
import numpy as np
import grpc
import tensorflow as tf
from tensorflow.keras.preprocessing import image
from tensorflow.keras.applications.resnet50 import preprocess_input
from tensorflow.keras.applications.resnet50 import decode_predictions
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_service_pb2_grpc

if __name__ == '__main__':
    channel = grpc.insecure_channel('localhost:8500')
    stub = prediction_service_pb2_grpc.PredictionServiceStub(channel)
    img_file = tf.keras.utils.get_file(
        "./kitten_small.jpg",
        "https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/docs/images/
↪kitten_small.jpg")
    img = image.load_img(img_file, target_size=(224, 224))
    img_array = preprocess_input(image.img_to_array(img)[None, ...])
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'resnet50_inf1'
    request.inputs['input'].CopyFrom(
        tf.contrib.util.make_tensor_proto(img_array, shape=img_array.shape))
    result = stub.Predict(request)
    prediction = tf.make_ndarray(result.outputs['output'])
    print(decode_predictions(prediction))
```

For Tensorflow 2.x:

```
import numpy as np
import grpc
import tensorflow as tf
from tensorflow.keras.preprocessing import image
from tensorflow.keras.applications.resnet50 import preprocess_input
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_service_pb2_grpc
from tensorflow.keras.applications.resnet50 import decode_predictions

tf.keras.backend.set_image_data_format('channels_last')

if __name__ == '__main__':
    channel = grpc.insecure_channel('localhost:8500')
    stub = prediction_service_pb2_grpc.PredictionServiceStub(channel)
    img_file = tf.keras.utils.get_file(
        "./kitten_small.jpg",
        "https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/docs/images/
↪kitten_small.jpg")
    img = image.load_img(img_file, target_size=(224, 224))
    img_array = preprocess_input(image.img_to_array(img)[None, ...])
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'resnet50_inf1'
    request.inputs['input_1'].CopyFrom(
        tf.make_tensor_proto(img_array, shape=img_array.shape))
    result = stub.Predict(request)
    prediction = tf.make_ndarray(result.outputs['output_1'])
    print(decode_predictions(prediction))
```

9.13 TensorFlow 2.x (tensorflow-neuron) Tracing API

The Neuron tracing API enables tracing TensorFlow 2.x models for deployment on AWS Machine Learning Accelerators.

9.13.1 Method

`tensorflow.neuron.trace`

9.13.2 Description

Trace a `keras.Model` or a Python callable that can be decorated by `tf.function`, and return an AWS-Neuron-optimized `keras.Model` that can execute on AWS Machine Learning Accelerators. Tracing is ideal for `keras.Model` that accepts a list of `tf.Tensor` objects and returns a list of `tf.Tensor` objects. It is expected that users will provide example inputs, and the `trace` function will execute `func` symbolically and convert it to a `keras.Model`.

The returned `keras.Model` will support inference only. Attributes or variables held by the original function or `keras.Model` will be dropped.

The returned `keras.Model` can be exported as SavedModel and served using TensorFlow Serving. Please see tensorflow-serving for more information about exporting to saved model and serving using TensorFlow Serving.

Options can be passed to Neuron compiler via the environment variable `NEURON_CC_FLAGS`. For example, the syntax `env NEURON_CC_FLAGS="--neuroncore-pipeline-cores=4"` directs Neuron compiler to compile each subgraph to fit in the specified number of NeuronCores. This number can be less than the total available NeuronCores on an Inf1 instance. See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.

9.13.3 Arguments

- **func:** The `keras.Model` or function to be traced.
- **example_inputs:** A `tf.Tensor` or a tuple/list/dict of `tf.Tensor` objects for tracing the function. When `example_inputs` is a `tf.Tensor` or a list of `tf.Tensor` objects, we expect `func` to have calling signature `func(example_inputs)`. Otherwise, the expectation is that inference on `func` is done by calling `func(*example_inputs)` when `example_inputs` is a `tuple`, or `func(**example_inputs)` when `example_inputs` is a `dict`. The case where `func` accepts mixed positional and keyword arguments is currently unsupported.
- **subgraph_builder_function:** (Optional) A callable with signature

  `subgraph_builder_function(node : NodeDef) -> bool` (`NodeDef` is defined in tensorflow/core/framework/node_def.proto)

  that is used as a call-back function to determine which part of the tensorflow GraphDef given by tracing `func` will be placed on Machine Learning Accelerators.

  If `subgraph_builder_function` is not provided, then `trace` will automatically place operations on Machine Learning Accelerators or on CPU to maximize the execution efficiency.

  If it is provided, and `subgraph_builder_function(node)` returns `True`, and placing `node` on Machine Learning Accelerators will not cause deadlocks during execution, then `trace` will place `node` on Machine Learning Accelerators. If `subgraph_builder_function(node)` returns `False`, then `trace` will place `node` on CPU.

9.13.4 Special Flags

These are flags that get passed directly to the Neuron tracing API (rather than the Neuron Compiler). The flags are still passed via the environment variable `NEURON_CC_FLAGS`.

- **workdir:** example usage - `NEURON_CC_FLAGS='--workdir ./artifacts'` will create a folder named artifacts in the current directory and save artifacts that can be used for debug.
- **dynamic-batch-size:** example usage - `NEURON_CC_FLAGS='--dynamic-batch-size'` A flag to allow Neuron graphs to consume variable sized batches of data. Dynamic sizing is restricted to the 0th dimension of a tensor.
- **extract-weights (EXPERIMENTAL):** example usage - `NEURON_CC_FLAGS='--extract-weights'` will reduce the compiled model's protobuf size by taking the weights out of the protobuf. Useful for compiling large models that would exceed the 2GB protobuf size limit. This feature is experimental. Model performance is not guaranteed and the flag does not work in combination with `--neuroncore-pipeline-cores`, `--dynamic-batch-size`, and models with multiple NEFFs. Compiles models for the inf1.2xlarge instance.

9.13.5 Returns

- An AWS-Neuron-optimized `keras.Model`.

9.13.6 Example Usage

```
import tensorflow as tf
import tensorflow.neuron as tfn

input0 = tf.keras.layers.Input(3)
dense0 = tf.keras.layers.Dense(3)(input0)
model = tf.keras.Model(inputs=[input0], outputs=[dense0])
example_inputs = tf.random.uniform([1, 3])
model_neuron = tfn.trace(model, example_inputs)  # trace

model_dir = './model_neuron'
model_neuron.save(model_dir)
model_neuron_reloaded = tf.keras.models.load_model(model_dir)
```

9.13.7 Example Usage with Manual Device Placement Using *subgraph_builder_function*

```
import tensorflow as tf
import tensorflow.neuron as tfn

input0 = tf.keras.layers.Input(3)
dense0 = tf.keras.layers.Dense(3)(input0)
reshape0 = tf.keras.layers.Reshape([1, 3])(dense0)
output0 = tf.keras.layers.Dense(2)(reshape0)
model = tf.keras.Model(inputs=[input0], outputs=[output0])
example_inputs = tf.random.uniform([1, 3])

def subgraph_builder_function(node):
    return node.op == 'MatMul'
```

(continues on next page)

(continued from previous page)

```
model_neuron = tfn.trace(
    model, example_inputs,
    subgraph_builder_function=subgraph_builder_function,
)
```

Important: Although the old API `tensorflow.neuron.saved_model.compile` is still available under tensorflow-neuron 2.x, it supports only the limited capabilities of `tensorflow.neuron.trace` and will be deprecated in future releases.

9.14 TensorFlow 1.x (`tensorflow-neuron`) Compilation API

The Neuron compilation API for TensorFlow 1.x enables compilation of saved model to an Inferentia target.

9.14.1 Method

`tensorflow.neuron.saved_model.compile`

9.14.2 Description

Within the graph or subgraph, the compile method selects and send Neuron-supported operations to Neuron-Compiler for compilation and saves the compiled artifacts in the graph. Uncompilable operations are kept as original operations for framework execution.

The compiled graph can be exported to saved model and served using TensorFlow Serving. Please see tensorflow-serving for more information about exporting to saved model and serving using TensorFlow Serving.

Options can be passed to Neuron compiler via the compile function. For example, the "`--neuroncore-pipeline-cores`" option directs Neuron compiler to compile each subgraph to fit in the specified number of NeuronCores. This number can be less than the total available NeuronCores on an Inf1 instance. See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.

9.14.3 Arguments

- **model_dir:** The path of the original `SavedModel`.
- **new_model_dir:** The path to which the Neuron-optimized `SavedModel` will be stored.
- **batch_size:** (Optional) Positive integer representing batch size used in inference. The default value is 1.
- **model_shape_feed_dict:** (Optional) Dictionary {str: list} used for inferring tensor shapes. Keys should match model input names. Values are lists of positive integers representing model input tensor shapes.
- **model_feed_dict:** (Optional) Dictionary {str: numpy.array} used for inference. Useful for inferring tensor shapes. Keys should match model input names. Values are numpy arrays that can be fed as inputs to the `SavedModel`.

- **tags:** (Optional) Iterable of strings to identify the required `MetaGraphDef`. These should correspond to the tags used when saving the variables using the `SavedModel save()` API. Default is to use the first `tag_set` available in the `SavedModel`.
- **signature_def_key:** (Optional) String specifying the `signature_def` to use. Default is to use 'serving_default' or the first `signature_def` corresponding to `tags`.
- **minimum_segment_size:** (Optional) Integer indicating the minimum number of operations in an NeuronOp.
- **no_fuse_ops:** (Optional) None or iterable of strings (unordered) representing names of operations that are forcibly placed on CPU.
- **compiler_args:** (Optional) List of strings representing neuron-cc compiler arguments. Note that these arguments apply to all subgraphs generated by whitelist partitioning. For example, use `compiler_args=['--neuroncore-pipeline-cores', '4']` to set number of NeuronCores per subgraph to 4. See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.
- **compiler_workdir:** (Optional) String representing work directory of the neuron-cc compiler.

9.14.4 Returns

- Dictionary with operator counts before/after optimization.
- Operator count statistics are displayed to show original count, post-optimization count, and the number placed on Neuron runtime. For example:

```
INFO:tensorflow:Number of operations in TensorFlow session: 3978
INFO:tensorflow:Number of operations after tf.neuron optimizations: 555
INFO:tensorflow:Number of operations placed on Neuron runtime: 554
```

9.14.5 Example Usage

```
import shutil
import tensorflow.neuron as tfn
saved_model_path = "<saved model path>"
compiled_saved_model_path = "<compiled saved model path>"
shutil.rmtree(compiled_saved_model_path, ignore_errors=True)
tfn.saved_model.compile(saved_model_path, compiled_saved_model_path)
```

9.15 TensorFlow Neuron (`tensorflow-nueron`) Auto Multicore Replication (Experimental)

The Neuron auto multicore replication Python API enables modifying TensorFlow 2.x traced models so that they can be automatically replicated across multiple cores. For Tensorflow-Serving models and TensorFlow 1.x models, see *TensorFlow Neuron TF1.x/TF2.x (tensorflow-nueron TF1.x/TF2.x) Auto Multicore Replication CLI (Experimental)*

Table of contents

- *TensorFlow Neuron TF 2.x (`tensorflow-nueron TF2.x`) Auto Multicore Replication Python API (Experimental)*
- *TensorFlow Neuron TF1.x/TF2.x (`tensorflow-nueron TF1.x/TF2.x`) Auto Multicore Replication CLI (Experimental)*

9.15.1 TensorFlow Neuron TF 2.x (`tensorflow-nueron TF2.x`) Auto Multicore Replication Python API (Experimental)

Method

`tensorflow.neuron.auto_multicore`

Description

Converts an existing AWS-Neuron-optimized `keras.Model` and return an auto-replication tagged AWS-Multicore-Neuron-optimized `keras.Model` that can execute on AWS Machine Learning Accelerators. Like the traced model, the returned `keras.Model` will support inference only. Attributes or variables held by the original function or `keras.Model` will be dropped.

The auto model replication feature in TensorFlow-Neuron enables you to create a model once and the model parallel replication would happen automatically. The desired number of cores can be less than the total available NeuronCores on an Inf1 instance but not less than 1. This reduces framework memory usage as you are not loading the same model multiple times manually. Calls to the returned model will execute the call on each core in a round-robin fashion.

The returned `keras.Model` can be exported as SavedModel and served using TensorFlow Serving. Please see tensorflow-serving for more information about exporting to saved model and serving using TensorFlow Serving.

Note that the automatic replication will only work on models compiled with pipeline size 1: via `--neuroncore-pipeline-cores=1`. If auto replication is not enabled, the model will default to replicate on up to 4 cores.

See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.

Arguments

- **func:** The `keras.Model` or function to be traced.
- **example_inputs:** A `tf.Tensor` or a tuple/list/dict of `tf.Tensor` objects for tracing the function. When `example_inputs` is a `tf.Tensor` or a list of `tf.Tensor` objects, we expect `func` to have calling signature `func(example_inputs)`. Otherwise, the expectation is that inference on `func` is done by calling `func(*example_inputs)` when `example_inputs` is a `tuple`, or `func(**example_inputs)` when `example_inputs` is a `dict`. The case where `func` accepts mixed positional and keyword arguments is currently unsupported.
- **num_cores:** The desired number of cores where the model will be automatically replicated across

Returns

- An AWS-Multicore-Neuron-optimized `keras.Model`.

Example Python API Usage for TF2.x traced models:

```
input0 = tf.keras.layers.Input(3)
dense0 = tf.keras.layers.Dense(3)(input0)
inputs = [input0]
outputs = [dense0]
model = tf.keras.Model(inputs=inputs, outputs=outputs)
input0_tensor = tf.random.uniform([1, 3])
model_neuron = tfn.trace(model, input0_tensor)

num_cores = 4
multicore_model = tfn.auto_multicore(model_neuron, input0_tensor, num_cores=num_cores)
multicore_model(input0_tensor)
```

Example Python API Usage for TF2.x saved models:

```
from tensorflow.python import saved_model

input0_tensor = tf.random.uniform([1, 3])
num_cores = 4
reload_model = saved_model.load(model_dir)
multicore_model = tfn.auto_multicore(reload_model, input0_tensor, num_cores=num_cores)
```

9.15.2 TensorFlow Neuron TF1.x/TF2.x (`tensorflow-nueron TF1.x/TF2.x`) Auto Multicore Replication CLI (Experimental)

The Neuron auto multicore replication CLI enables modifying TensorFlow 1.x and Tensorflow 2.x traced saved models so that they can be automatically replicated across multiple cores. By performing this call on Tensorflow Saved Models, we can support both Tensorflow-Serving and Tensorflow 1.x without significant modifications to the code. Note that the python API does not support Tensorflow 1.x.

Method

```
tf-neuron-auto-multicore MODEL_DIR --num_cores NUM_CORES --new_model_dir NEW_MODEL_DIR
```

Arguments

- **MODEL_DIR:** The directory of a saved AWS-Neuron-optimized `keras.Model`.
- **NUM_CORES:** The desired number of cores where the model will be automatically replicated across
- **NEW_MODEL_DIR:** The directory of where the AWS-Multicore-Neuron-optimized `keras.Model` will be saved

Example CLI Usage for TF 1.x and Tensorflow-Serving saved models:

```
tf-neuron-auto-multicore ./resnet --num_cores 8 --new_model_dir ./modified_resnet
```

This document lists the release notes for the tensorflow-neuron 1.x package.

9.16.1 Known Issues and Limitations - updated 08/12/2021

- Support on serialized TensorFlow 2.x custom operators is currently limited. Serializing some operators registered from TensorFlow-text through TensorFlow Hub is going to cause failure in tensorflow.neuron.trace.
- Issue: When compiling large models, user might run out of memory and encounter this fatal error.

```
terminate called after throwing an instance of 'std::bad_alloc'
```

Solution: run compilation on a c5.4xlarge instance type or larger.

- Issue: When upgrading `tensorflow-neuron` with `pip install tensorflow-neuron --upgrade`, the following error message may appear, which is caused by `pip` version being too low.

```
Could not find a version that satisfies the requirement TensorFlow<1.16.0,>=1.15.0 (from␣
↪tensorflow-neuron)
```

Solution: run a `pip install pip --upgrade` before upgrading `tensorflow-neuron`.

- Issue: Some Keras routines throws the following error:

```
AttributeError: 'str' object has no attribute 'decode'.
```

Solution: Please downgrade *h5py* by *pip install 'h5py<3'*. This is caused by https://github.com/TensorFlow/TensorFlow/issues/44467.

9.16.2 tensorflow-neuron 1.x release [2.4.0.0]

Date: 11/23/2022

- Introduce `tf-neuron-auto-multicore` tool to enable automatic data parallel on multiple NeuronCores.
- Deprecated the NEURONCORE_GROUP_SIZES environment variable.
- Minor bug fixes.

9.16.3 tensorflow-neuron 1.x release [2.3.0.0]

Date: 04/29/2022

- Minor bug fixes.

9.16.4 tensorflow-neuron 1.x release [2.1.14.0]

Date: 03/25/2022

- Minor bug fixes.

9.16.5 tensorflow-neuron 1.x release [2.1.14.0]

Date: 02/17/2022

- Minor bug fixes.

9.16.6 tensorflow-neuron 1.x release [2.1.13.0]

Date: 02/16/2022

- Fixed a bug that caused a memory leak. The memory leak was approximately 128b for each inference and exists in all versions of TensorFlow Neuron versions part of Neuron 1.16.0 to Neuron 1.17.0 releases. see pre-release-content for exact versions included in each release.

9.16.7 tensorflow-neuron 1.x release [2.1.6.0]

Date: 01/20/2022

- Enhanced auto data parallel (e.g. when using NEURONCORE_GROUP_SIZES=X,Y,Z,W) to support edge cases.
- Added new operators support. see *TensorFlow Neuron (tensorflow-neuron (TF1.x)) Supported operators*.

9.16.8 tensorflow-neuron 1.x release [2.0.4.0]

Date: 11/05/2021

- Updated Neuron Runtime (which is integrated within this package) to `libnrt 2.2.18.0` to fix a container issue that was preventing the use of containers when /dev/neuron0 was not present. See details here neuron-runtime-release-notes.

9.16.9 tensorflow-neuron 1.x release [2.0.3.0]

Date: 10/27/2021

New in this release

- TensorFlow 1.x (`tensorflow-neuron`) now support Neuron Runtime 2.x (`libnrt.so` shared library) only.

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.

- Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

Resolved Issues

- Fix neuron-cc argument handling bug when nothing can be compiled.
- Fixing the support of cast operators applied after constants, by Introducing support of constant-folding pass before Neuron auto-mixed-precision.

9.16.10 [1.15.5.1.5.1.0]

Date: 07/02/2021

New in this release

- Bug fixes regarding scalar inputs/outputs.
- Minor performance improvements when dynamic batch size is turned on or when model is small.

9.16.11 [1.15.5.1.4.0.0]

Date: 05/28/2021

New in this release

- Reduce the amount of input/output data movement during inference.
- Improve parallelism for dynamic batch size inference by adopting a new sharding mechanism.
- Reduce the amount of host memory usage during inference.
- tfn.saved_model.compile now generates correct code when operator Split is used as output.
- tfn.saved_model.compile now properly reads input tensor shape information from SignatureDef proto.
- tfn.saved_model.compile now terminates properly when neuron-cc compiler argument is passed but there is no successful compilation.
- Fix bug on some wrong internal tensor names when neuron-cc compiler crashes.
- Other minor bug fixes.

9.16.12 [1.15.5.1.3.3.0]

Date: 05/01/2021

New in this release

1. Minor enhancements.

9.16.13 [1.15.5.1.2.9.0]

Date: 03/04/2021

New in this release

1. Minor enhancements.

9.16.14 [1.15.5.1.2.8.0]

Date: 02/24/2021

New in this release

1. Fix for CVE-2021-3177.

9.16.15 [1.15.5.1.2.2.0]

Date: 01/30/2021

New in this release

1. Bug fixes and internal refactor.
2. Bump TensorFlow base package version to 1.15.5.
3. Introduced a new argument `convert_constants_to_variables` to the compilation API `tfn.saved_model.compile`. Setting it to `True` can address the issue of large constants consuming too much memory in the TensorFlow runtime.

9.16.16 [1.15.4.1.1.3.0]

Date: 12/23/2020

New in this release

1. Improved logging during *tfn.saved_model.compile* to display *neuron-cc* compilation progress.
2. Small performance improvement in some edge cases by optimizing the NeuronCore-executable assignment mechanism.

9.16.17 [1.15.4.1.0.2168.0]

Date: 11/17/2020

New in this release

1. tensorflow-neuron is now a plugin package that can be used together with TensorFlow~=1.15.0 built with `GLIBCXX_USE_CXX11_ABI=0`.
2. Improved logging during `tfn.saved_model.compile` to display `neuron-cc` logging file path, which is useful for tracking `neuron-cc` compilation progress.
3. Small performance improvement by utilizing shared memory more efficiently.

9.16.18 [1.15.3.1.0.2043.0]

Date: 09/22/2020

New in this release

1. tensorflow-neuron now automatically enables data parallel mode on four cores in one Inferentia. In `TensorFlow-model-server-neuron`, most models can now fully utilize four cores automatically. In Python TensorFlow, running threaded inference using `>=4` Python threads in the same TensorFlow Session lead to full utilization of four cores.
2. tensorflow-neuron now tries to enable dynamic batch size automatically for a limited number of models, such as ResNet50.
3. Improved logging during `tfn.saved_model.compile` to display input/output information about subgraphs that are going to be compiled by `neuron-cc`.

9.16.19 [1.15.3.1.0.1965.0]

Date: 08/08/2020

New in this release

Various minor improvements.

9.16.20 [1.15.3.1.0.1953.0]

Date: 08/05/2020

New in this release

Various minor improvements.

9.16.21 [1.15.3.1.0.1891.0]

Date: 07/16/2020

New in this release

This version contains a few bug fixes and user experience improvements.

Dependency change

1. Bump TensorFlow base package version number to 1.15.3
2. Add `TensorFlow >= 1.15.0, < 1.16.0` as an installation dependency so that packages depending on TensorFlow can be installed together with tensorflow-neuron without error

New Features

1. `tensorflow-neuron` now displays a summary of model performance when profiling is enable by setting environment variable `NEURON_PROFILE`

Resolved Issues

1. Environment variable `NEURON_PROFILE` can now be set to a non-existing path which will be automatically created
2. Fixed a bug in `tfn.saved_model.compile` that causes compilation failure when `dynamic_batch_size=True` is specified on a SavedModel with unknown rank inputs.

9.16.22 [1.15.2.1.0.1796.0]

Date 6/11/2020

New in this release

This version contains a few bug fixes.

Major New Features

Resolved Issues

1. Fixed a bug related with device placement. Now models with device information hardcoded to GPU can be successfully compiled with `tfn.saved_model.compile`
2. Fixed a bug in `tfn.saved_model.compile` that causes models containing Reshape operators not functioning correctly when it is compiled with `dynamic_batch_size=True`
3. Fixed a bug in `tfn.saved_model.compile` that causes models containing Table related operators to initialize incorrectly after compilation.

Known Issues and limitations

9.16.23 [1.15.2.1.0.1572.0]

Date: 5/11/2020

New in this release

This version contains some bug fixes and new features.

Major New Features

- tensorflow-neuron is now built on TensorFlow 1.15.2 instead of TensorFlow 1.15.0

Resolved Issues

- Fixed a bug that caused Neuron runtime resources to not all be released when a tensorflow-neuron process terminated with in-flight inferences
- Inference timeout value set at compile time is now correctly recognized at runtime

Known Issues and limitations

9.16.24 [1.15.0.1.0.1333.0]

Date: 3/26/2020

New in this release

Major New Features

- Improved performance between TensorFlow to Neuron runtime.

Resolved Issues

- Fixed a bug in Neuron runtime adaptor operator's shape function when dynamic batch size inference is enabled
- Framework method (tensorflow.neuron.saved-model.compile) improved handling of compiler timeout termination by letting it clean up before exiting.

Known Issues and limitations

9.16.25 [1.15.0.1.0.1240.0]

Date: 2/27/2020

New in this release

Major New Features

- Enabled runtime memory optimizations by default to improve inference performance, specifically in cases with large input/output tensors
- tfn.saved_model.compile now displays warning message instead of "successfully compiled" if less than 30% of operators are mapped to Inferentia
- Improve error messages. Runtime failure error messages are now more descriptive and also provide instructions to restart neuron-rtd when necessary.

Resolved Issues

Known Issues and Limitations

- Issue: When compiling a large model, may encounter.

```
terminate called after throwing an instance of 'std::bad_alloc'
```

Solution: run compilation on c5.4xlarge instance type or larger.

Other Notes

9.16.26 [1.15.0.1.0.997.0]

Date: 1/27/2020

New in this release

Major New Features

- Added support for NCHW pooling operators in tfn.saved_model.compile.

Resolved Issues

- Fixed GRPC transient status error issue.
- Fixed a graph partitioner issue with control inputs.

Known Issues and Limitations

- Issue: When compiling a large model, may encounter.

```
terminate called after throwing an instance of 'std::bad_alloc'
```

Solution: run compilation on c5.4xlarge instance type or larger.

Other Notes

9.16.27 [1.15.0.1.0.803.0]

Date: 12/20/2019

New in this release

Major New Features

Resolved Issues

- Improved handling of `tf.neuron.saved_model.compile` arguments

Known Issues and Limitations

Other Notes

9.16.28 [1.15.0.1.0.749.0]

Date: 12/1/2019

New in this release

Major New Features

Resolved Issues

- Fix race condition between model load and model unload when the process is killed
- Remove unnecessary GRPC calls when the process is killed

Known Issues and Limitations

- When compiling a large model, may encounter "terminate called after throwing an instance of 'std::bad_alloc'". Solution: run compilation on c5.4xlarge instance type or larger.
- The pip package `wrapt` may have a conflicting version in some installations. This is seen when this error occurs:

```
ERROR: Cannot uninstall 'wrapt'. It is a distutils installed project and thus we cannot␣
↪accurately determine which files belong to it which would lead to only a partial␣
↪uninstall.
```

To solve this, you can update wrapt to the newer version:

```
python3 -m pip install wrapt --ignore-installed
python3 -m pip install tensorflow-neuron
```

Within a Conda environment:

```
conda update wrapt
conda update tensorflow-neuron
```

Other Notes

9.16.29 [1.15.0.1.0.663.0]

Date: 11/25/2019

New in this release

This version is available only in released DLAMI v26.0 and is based on TensorFlow version 1.15.0. Please update to latest version.

Major New Features

Resolved Issues

Known Issues and Limits

Models Supported

The following models have successfully run on neuron-inferentia systems

1. BERT_LARGE and BERT_BASE
2. Transformer
3. Resnet50 V1/V2
4. Inception-V2/V3/V4

Other Notes

- Python versions supported:
  - 3.5, 3.6, 3.7
- Linux distribution supported:
  - Ubuntu 18, Amazon Linux 2

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

9.17 TensorFlow Neuron (`tensorflow-neuron (TF2.x)`) Release Notes

Table of contents

- *Known Issues and Limitations - updated 08/12/2021*

- *tensorflow-neuron 2.x release [1.6.8.0]*

This document lists the release notes for the tensorflow-neuron 2.x packages.

9.17.1 Known Issues and Limitations - updated 08/12/2021

- Support on serialized TensorFlow 2.x custom operators is currently limited. Serializing some operators registered from tensorflow-text through TensorFlow Hub is going to cause failure in tensorflow.neuron.trace.
- Memory leak exists on latest releases of TensorFlow Neuron for versions 2.1, 2.2, 2.3, and 2.4.
- Issue: When compiling large models, user might run out of memory and encounter this fatal error.

```
terminate called after throwing an instance of 'std::bad_alloc'
```

Solution: run compilation on a c5.4xlarge instance type or larger.

- Issue: When upgrading `tensorflow-neuron` with `pip install tensorflow-neuron --upgrade`, the following error message may appear, which is caused by `pip` version being too low.

```
Could not find a version that satisfies the requirement tensorflow<1.16.0,>=1.15.0 (from␣
↪tensorflow-neuron)
```

Solution: run a `pip install pip --upgrade` before upgrading `tensorflow-neuron`.

- Issue: Some Keras routines throws the following error:

```
AttributeError: 'str' object has no attribute 'decode'.
```

Solution: Please downgrade *h5py* by *pip install 'h5py<3'*. This is caused by https://github.com/TensorFlow/TensorFlow/issues/44467.

9.17.2 tensorflow-neuron 2.x release [2.4.0.0]

Date: 11/22/2022

- Experimental support for tracing models larger than 2 GB through environment variable `NEURON_CC_FLAGS='--extract-weights'`.
- Introduce `tfn.auto_multicore` Python API to enable automatic data parallel on multiple NeuronCores.
- Introduce `tf-neuron-auto-multicore` tool to enable automatic data parallel on multiple NeuronCores.
- Deprecated the NEURONCORE_GROUP_SIZES environment variable.
- Minor bug fixes.

9.17.3 tensorflow-neuron 2.x release [2.3.0.0]

Date: 04/29/2022

- Added support for Tensorflow 2.8.0.
- Added support for Slice operator
- The graph partitioner now prefers to place less compute intensive operators on CPU if the model already contains a large amount of compute intensive operators.
- Fixed Github issue #408, the fix solves data type handling bug in `tfn.trace` when the model contains Conv2D operators.

9.17.4 tensorflow-neuron 2.x release [2.2.0.0]

Date: 03/25/2022

- Updated TensorFlow 2.5 to version 2.5.3.
- Added support for TensorFlow 2.6 and 2.7.
- Added a warning message when calling `tfn.saved_model.compile` API. In tensorflow-neuron 2.x you should call *tensorflow.neuron.trace*. `tfn.saved_model.compile` API supports only partial functionality of *tensorflow.neuron.trace* and will be deprecated in the future.

9.17.5 tensorflow-neuron 2.x release [2.1.14.0]

Date: 02/17/2022

- Fixed a bug in TensorFlow Neuron versions 2.1, 2.2. 2.3 and 2.4. The fixed bug was causing a memory leak of 128 bytes for each inference.
- Improved warning message when calling deprecated compilation API under tensorflow-neuron 2.x.

9.17.6 tensorflow-neuron 2.x release [2.1.13.0]

Date: 02/16/2022

- Fixed a bug that caused a memory leak. The memory leak was approximately 128b for each inference and exists in all versions of TensorFlow Neuron versions part of Neuron 1.16.0 to Neuron 1.17.0 releases. see pre-release-content for exact versions included in each release. This release only addresses the leak in TensorFlow Neuron 2.5. Future release of TensorFlow Neuron will fix the leak in other versions as well (2.1, 2.2, 2.3, 2.4).

9.17.7 tensorflow-neuron 2.x release [2.1.6.0]

Date: 01/20/2022

- Updated TensorFlow 2.5 to version 2.5.2.
- Enhanced auto data parallel (e.g. when using NEURONCORE_GROUP_SIZES=X,Y,Z,W) to support edge cases.
- Fixed a bug that may cause tensorflow-neuron to generate in some cases scalar gather instruction with incorrect arguments.

9.17.8 tensorflow-neuron 2.x release [2.0.4.0]

Date: 11/05/2021

- Updated Neuron Runtime (which is integrated within this package) to `libnrt 2.2.18.0` to fix a container issue that was preventing the use of containers when /dev/neuron0 was not present. See details here neuron-runtime-release-notes.

9.17.9 tensorflow-neuron 2.x release [2.0.3.0]

Date: 10/27/2021

New in this release

- TensorFlow 2.x (`tensorflow-neuron`) now support Neuron Runtime 2.x (`libnrt.so` shared library) only.

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.

  - Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

- Updated TensorFlow 2.3.x from TensorFlow 2.3.3 to TensorFlow 2.3.4.
- Updated TensorFlow 2.4.x from TensorFlow 2.4.2 to TensorFlow 2.4.3.
- Updated TensorFlow 2.5.x from TensorFlow 2.5.0 to TensorFlow 2.5.1.

Resolved Issues

- Fix bug that can cause illegal compiler optimizations
- Fix bug that can cause dynamic-shape operators be placed on Neuron

9.17.10 tensorflow-neuron 2.x release [1.6.8.0]

Date: 08/12/2021

New in this release

- First release of TensorFlow 2.x integration, Neuron support now TensorFlow versions 2.1.4, 2.2.3, 2.3.3, 2.4.2, and 2.5.0.
- New public API tensorflow.neuron.trace: trace a TensorFlow 2.x keras.Model or a Python callable that can be decorated by tf.function, and return an AWS-Neuron-optimized keras.Model that can execute on AWS Machine Learning Accelerators.

  Please note that TensorFlow 1.x SavedModel compilation API tensorflow.neuron.saved_model.compile is not supported in tensorflow-neuron 2.x . It continues to function in tensorflow-neuron 1.15.x .
- Included versions:
  - tensorflow-neuron-2.5.0.1.6.8.0
  - tensorflow-neuron-2.4.2.1.6.8.0
  - tensorflow-neuron-2.3.3.1.6.8.0
  - tensorflow-neuron-2.2.3.1.6.8.0
  - tensorflow-neuron-2.1.4.1.6.8.0

9.18 TensorFlow Neuron (`tensorflow-neuron (TF2.x)`) Accelerated (torch-neuron) Python APIs and Graph Ops

This page lists TensorFlow 2.x Python APIs and graph operators that are accelerated by AWS Neuron. The lists are not exhaustive. TensorFlow 2.x Python APIs or graph operators that are not listed here may still be accelerated if they are composed of accelerated primitives, or they will be executed on CPU without significant acceleration. The TensorFlow Neuron integration contains an automatic operator-device-placement mechanism that strives to maximize the execution efficiency of your deep learning models on AWS Machine Learning ASIC instances.

9.18.1 Accelerated Python APIs

Module	Accelerated Python API	Comments
tf	tf.abs	
	tf.add	
	tf.add_n	
	tf.broadcast_static_shape	
	tf.cast	
	tf.constant	
	tf.convert_to_tensor	
	tf.cumsum	axis must be a compile-time constant.
	tf.einsum	
	tf.erf	
	tf.exp	
	tf.identity	
	tf.matmul	Uses float16/bfloat16 matmul with float32 accumulation.
	tf.maximum	
	tf.minimum	
	tf.multiply	
	tf.negative	
	tf.range	start, limit and delta arguments must be compile-time constants.
	tf.realdiv	
	tf.reciprocal	
	tf.reduce_all	axis must be a compile-time constant.
	tf.reduce_any	axis must be a compile-time constant.
	tf.reduce_max	axis must be a compile-time constant.
	tf.reduce_min	axis must be a compile-time constant.
	tf.reduce_prod	axis must be a compile-time constant.
	tf.reduce_sum	axis must be a compile-time constant.
	tf.reshape	shape argument must be a compile-time constant.
	tf.rsqrt	
	tf.scalar_mul	
	tf.shape	
	tf.shape_n	
	tf.sigmoid	
	tf.size	

continues on next page

Table 1 – continued from previous page

Module	Accelerated Python API	Comments
	tf.slice	size must be a compile-time constant. In addition, either begin must be a compile-time constant or size must be non-negative.
	tf.sqrt	
	tf.square	
	tf.squared_difference	
	tf.squeeze	
	tf.stack	
	tf.stop_gradient	
	tf.strided_slice	
	tf.tanh	
	tf.tensordot	
	tf.to_bfloat16	
	tf.to_float	
	tf.truediv	
tf.layers	tf.layers.batch_normalization	
	tf.layers.dense	
	tf.layers.flatten	
tf.nn	tf.nn.batch_normalization	
	tf.nn.bias_add	
	tf.nn.dropout	Always treated as tf.identity during inference.
	tf.nn.fused_batch_norm	
	tf.nn.leaky_relu	
	tf.nn.relu	
	tf.nn.relu6	
	tf.nn.relu_layer	
	tf.nn.softmax

CHAPTER

TEN

MXNET NEURON

MXNet Neuron unlocks high-performance and cost-effective deep learning acceleration on AWS Trainium-based and Inferentia-based Amazon EC2 instances.

MXNet Neuron enables native MXNet models to be accelerated on Neuron devices, so you can use your existing framework application and get started easily with minimal code changes.

Inference

Setup Guide for Inf1

This document is relevant for: `Inf1`

10.1 Install MXNet Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

10.1.1 Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

MXNet 1.8.0

# Activate MXNet
source activate aws_neuron_mxnet_p36
```

10.1.2 Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

MXNet 1.8.0

Ubuntu 18 AMI/Ubuntu 20 AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
#######################################################
#   Only for Ubuntu 20 - Install Python3.7

Amazon Linux 2 DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Neuron is pre-installed on Deep Learning AMI (DLAMI), latest DLAMI version may not␣
↪include latest Neuron versions
# To update to latest Neuron version, follow "Update to latest release" instruction on␣
↪Neuron documentation

# Activate MXNet
source activate aws_neuron_mxnet_p36
```

10.1.3 Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

This document is relevant for: `Inf1`

10.2 Update to latest MXNet Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

10.2.1 Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

MXNet 1.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Update OS packages

```

10.2.2 Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

MXNet 1.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Activate a Python 3.7 virtual environment where Neuron pip packages were installed

```

10.2.3 Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

10.3.1 Install MXNet Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

This document is relevant for: `Inf1`

10.3.2 Install MXNet Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

MXNet 1.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

MXNet 1.5.1

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
#######################################################
#   Only for Ubuntu 20 - Install Python3.7
#
# sudo add-apt-repository ppa:deadsnakes/ppa
# sudo apt-get install python3.7
#
#######################################################
# Install Python venv and activate Python virtual environment to install
# Neuron pip packages.
sudo apt-get install -y python3.7-venv g++
python3.7 -m venv mxnet_venv
source mxnet_venv/bin/activate
pip install -U pip

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron MXNet
pip install mxnet_neuron==1.5.1.1.9.0.0 neuron-cc==1.10.3.0
```

Amazon Linux AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Install Python venv and activate Python virtual environment to install
# Neuron pip packages.
sudo yum install -y python3.7-venv gcc-c++
python3.7 -m venv mxnet_venv
source mxnet_venv/bin/activate
pip install -U pip

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron MXNet
pip install mxnet_neuron==1.5.1.1.9.0.0 neuron-cc==1.10.3.0
```

Ubuntu DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Activate MXNet
source activate aws_neuron_mxnet_p36

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron MXNet
pip install mxnet_neuron==1.5.1.1.9.0.0 neuron-cc==1.10.3.0
```

Amazon Linux DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Activate MXNet
source activate aws_neuron_mxnet_p36

# Set Pip repository  to point to the Neuron repository
pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

#Install Neuron MXNet
pip install mxnet_neuron==1.5.1.1.9.0.0 neuron-cc==1.10.3.0
```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

MXNet 1.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Configure Linux for Neuron repository updates
. /etc/os-release
sudo tee /etc/apt/sources.list.d/neuron.list > /dev/null <<EOF
deb https://apt.repos.neuron.amazonaws.com ${VERSION_CODENAME} main
EOF

This document is relevant for: `Inf1`

10.3.3 Install MXNet Neuron

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- For an example of how to install Neuron components in a container, see tutorial-docker-env-setup and our neuron-containers documentation for more details.

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

MXNet 1.8.0

Ubuntu AMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

10.3.5 Install MXNet Neuron (Neuron 1.15.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

#Install Neuron MXNet
pip install mxnet_neuron==1.5.1.1.6.5.0 neuron-cc==1.6.13.0
```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

10.3.6 Install MXNet Neuron (Neuron 1.15.1)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

MXNet 1.8.0

```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

10.3.7 Install MXNet Neuron (Neuron 1.15.0)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

#Install Neuron MXNet
pip install mxnet_neuron==1.5.1.1.6.5.0 neuron-cc==1.6.13.0
```

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

```

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

10.3.8 Install MXNet Neuron (Neuron 1.14.2)

Table of contents

- *Develop on AWS ML accelerator instance*
- *Compile on compute instance*
- *Deploy on AWS ML accelerator instance*

Develop on AWS ML accelerator instance

The simplest environment setup for model development installs all Neuron SDK components directly on an AWS ML accelerator instance: the Neuron framework extensions, compiler, runtime, and tools. This will allow you to compile, execute, and performance tune your model, all in the same instance. This is the recommended workflow when first starting to work with Neuron device or when optimizing a model.

MXNet 1.8.0

Compile on compute instance

If model compilation occurs outside the model deployment environment, you can install only the Neuron framework extensions and the compiler on any compute instance. This setup is helpful when compiling large complex models that require large amount of memory or during a CICD process where models are compiled in a separate step, prior to deployment.

Deploy on AWS ML accelerator instance

During deployment it can be beneficial to reduce the number of components installed in the system. For use-cases where only inference is necessary (compilation is already complete), only the framework and runtime should be installed.

10.4 Running Neuron Apache MXNet (Incubating) ResNet50 on Inferentia

10.4.1 Introduction:

In this tutorial we will compile and deploy ResNet50 model for Inferentia. In this tutorial we provide two main sections:

1.Compile the ResNet50 model.

2.Infer the compiled model.

Before running the following verify this Jupyter notebook is running "conda_aws_neuron_mxnet_p36" kernel. You can select the Kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page. Neuron supports Python module, Symbol APIs and the C predict API. The following quick start example uses the Symbol API.

Warning

This tutorial was tested on MXNet-1.5

MXNet-1.5 entered maintenance mode and require Neuron runtime 1.0, please see : MXNet-1.5 enters maintainence mode

To setup development environment for MXNet-1.5 see installation instructions for Neuron 1.15.1 : Neuron-1.15.1 MXNet install

10.4.2 Compile model on Neuron

The following step will compile the resnet50 model. Compilation will take a few minutes on inf1.6xlarge. At the end of compilation, the files resnet-50_compiled-0000.params and resnet-50_compiled-symbol.json will be created in local directory.

[ ]:
```
import mxnet as mx
import numpy as np

path='http://data.mxnet.io/models/imagenet/'
mx.test_utils.download(path+'resnet/50-layers/resnet-50-0000.params')
mx.test_utils.download(path+'resnet/50-layers/resnet-50-symbol.json')
sym, args, aux = mx.model.load_checkpoint('resnet-50', 0)

# Compile for Inferentia using Neuron
inputs = { "data" : mx.nd.ones([1,3,224,224], name='data', dtype='float32') }
sym, args, aux = mx.contrib.neuron.compile(sym, args, aux, inputs)
```

(continues on next page)

(continued from previous page)

```
#save compiled model
mx.model.save_checkpoint("resnet-50_compiled", 0, sym, args, aux)
```

[ ]:
```
!ls
```

10.4.3 Deploy on Inferentia

Using same instance to deploy the model.

[ ]:
```
import mxnet as mx
import numpy as np

path='http://data.mxnet.io/models/imagenet/'
mx.test_utils.download(path+'synset.txt')

fname = mx.test_utils.download('https://raw.githubusercontent.com/awslabs/mxnet-model-
↪server/master/docs/images/kitten_small.jpg?raw=true')
img = mx.image.imread(fname)# convert into format (batch, RGB, width, height)
img = mx.image.imresize(img, 224, 224) # resize
img = img.transpose((2, 0, 1)) # Channel first
img = img.expand_dims(axis=0) # batchify
img = img.astype(dtype='float32')

sym, args, aux = mx.model.load_checkpoint('resnet-50_compiled', 0)
softmax = mx.nd.random_normal(shape=(1,))
args['softmax_label'] = softmax
args['data'] = img

# Inferentia context
ctx = mx.neuron()

exe = sym.bind(ctx=ctx, args=args, aux_states=aux, grad_req='null')

with open('synset.txt', 'r') as f:
     labels = [l.rstrip() for l in f]

exe.forward(data=img)
prob = exe.outputs[0].asnumpy()# print the top-5
prob = np.squeeze(prob)
a = np.argsort(prob)[::-1]
for i in a[0:5]:
     print('probability=%f, class=%s' %(prob[i], labels[i]))

# Sample output will look like below:
#probability=0.634792, class=n02123045 tabby, tabby cat
#probability=0.193601, class=n02123159 tiger cat
#probability=0.103627, class=n02124075 Egyptian cat
#probability=0.031604, class=n02127052 lynx, catamount
#probability=0.015892, class=n02129604 tiger, Panthera tigris
```

This document is relevant for: `Inf1`

10.5 Tutorial: Neuron Apache MXNet (Incubating) Model Serving

This MXNet Neuron Model Serving (MMS) example is adapted from the MXNet vision service example which uses pretrained squeezenet to perform image classification: https://github.com/awslabs/multi-model-server/tree/master/examples/mxnet_vision.

Before starting this example, please ensure that Neuron-optimized MXNet version mxnet-neuron is installed along with Neuron Compiler.

10.5.1 Warning

If you are using MXNet-1.5, please note that MXNet-1.5 entered maintenance mode and require Neuron Runtime 1.x, please see maintenance_mxnet_1_5. To setup development environment for MXNet-1.5 see installation instructions at mxnet-setup.

If using DLAMI, you can activate the environment aws_neuron_mxnet_p36 and skip the installation part in the first step below.

1. First, install Java runtime and multi-model-server:

```
cd ~/
# sudo yum -y install -q jre # for AML2
sudo apt-get install -y -q default-jre  # for Ubuntu
pip install multi-model-server
```

Download the example code:

```
git clone https://github.com/awslabs/multi-model-server
cd ~/multi-model-server/examples/mxnet_vision
```

2. Compile ResNet50 model to Inferentia target by saving the following Python script to compile_resnet50.py and run "`python compile_resnet50.py`"

```
from packaging import version
import numpy as np
import mxnet as mx

mxnet_version = version.parse(mx.__version__)
if mxnet_version >= version.parse("1.8"):
   import mx_neuron as neuron
else:
   from mxnet.contrib import neuron

path='http://data.mxnet.io/models/imagenet/'
mx.test_utils.download(path+'resnet/50-layers/resnet-50-0000.params')
mx.test_utils.download(path+'resnet/50-layers/resnet-50-symbol.json')
mx.test_utils.download(path+'synset.txt')

nn_name = "resnet-50"

#Load a model
sym, args, auxs = mx.model.load_checkpoint(nn_name, 0)

#Define compilation parameters
```

(continues on next page)

(continued from previous page)

```
#  - input shape and dtype
inputs = {'data' : mx.nd.zeros([1,3,224,224], dtype='float32') }

# compile graph to inferentia target
csym, cargs, cauxs = neuron.compile(sym, args, auxs, inputs)

# save compiled model
mx.model.save_checkpoint(nn_name + "_compiled", 0, csym, cargs, cauxs)
```

3. Prepare signature file `signature.json` to configure the input name and shape:

```
{
  "inputs": [
    {
      "data_name": "data",
      "data_shape": [
        1,
        3,
        224,
        224
      ]
    }
  ]
}
```

4. Prepare `synset.txt` which is a list of names for ImageNet prediction classes:

```
curl -O https://s3.amazonaws.com/model-server/model_archive_1.0/examples/squeezenet_v1.1/
↪synset.txt
```

5. Create custom service class following template in model_server_template folder:

```
cp -r ../model_service_template/* .
```

Edit `mxnet_model_service.py` to use the appropriate context.

Make the following change:

```
from packaging import version

mxnet_version = version.parse(mx.__version__)
if mxnet_version >= version.parse("1.8"):
   import mx_neuron as neuron
self.mxnet_ctx = mx.neuron()
```

Comment out the existing context set:

```
#self.mxnet_ctx = mx.cpu() if gpu_id is None else mx.gpu(gpu_id)
```

Also, comment out unnecessary data copy for model_input in `mxnet_model_service.py`:

```
#model_input = [item.as_in_context(self.mxnet_ctx) for item in model_input]
```

6. Package the model with model-archiver:

```
cd ~/multi-model-server/examples
model-archiver --force --model-name resnet-50_compiled --model-path mxnet_vision --
↪handler mxnet_vision_service:handle
```

7. Start MXNet Model Server (MMS) and load model using RESTful API. Please ensure that Neuron RTD is running with default settings (see rtd-getting-started):

```
cd ~/multi-model-server/
multi-model-server --start --model-store examples
# Pipe to log file if you want to keep a log of MMS
curl -v -X POST "http://localhost:8081/models?initial_workers=1&max_workers=1&
↪synchronous=true&url=resnet-50_compiled.mar"
sleep 10 # allow sufficient time to load model
```

Each worker requires a NeuronCore group that can accommodate the compiled model. Additional workers can be added by increasing max_workers configuration as long as there are enough NeuronCores available. Use `neuron-top` to see which models are loaded on specific NeuronCores.

8. Test inference using an example image:

```
curl -O https://raw.githubusercontent.com/awslabs/multi-model-server/master/docs/images/
↪kitten_small.jpg
curl -X POST http://127.0.0.1:8080/predictions/resnet-50_compiled -T kitten_small.jpg
```

You will see the following output:

```
[
  {
    "probability": 0.6375716328620911,
    "class": "n02123045 tabby, tabby cat"
  },
  {
    "probability": 0.1692783385515213,
    "class": "n02123159 tiger cat"
  },
  {
    "probability": 0.12187337130308151,
    "class": "n02124075 Egyptian cat"
  },
  {
    "probability": 0.028840631246566772,
    "class": "n02127052 lynx, catamount"
  },
  {
    "probability": 0.019691042602062225,
    "class": "n02129604 tiger, Panthera tigris"
  }
]
```

9. To cleanup after test, issue a delete command via RESTful API and stop the model server:

```
curl -X DELETE http://127.0.0.1:8081/models/resnet-50_compiled

multi-model-server --stop
```

This document is relevant for: `Inf1`

10.6 MXNet 1.8: Getting Started with Gluon Tutorial

In this tutorial you will compile and deploy resnet-50 using the newly supported MXNet 1.8 and Gluon API on an Inf1 instance. This tutorial is only supported with MXNet 1.8.

This Jupyter notebook should be run on an inf1.6xlarge instance since you will be loading and compiling several large models.

To run this tutorial, please make sure you deactivate any existing MXNet conda environments you already using. Install MXNet 1.8 by following the instructions at MXNet Setup Guide. You would also need to change your kernel to use the correct Python environment setup earlier by clicking Kerenel->Change Kernel->Python (Neuron MXNet)

10.7 Compile

A trained model must be compiled to Inferentia target before it can run on Inferentia. In this step we compile a pre-trained ResNet50 and export it as a compiled MXNet checkpoint.

Compilation will take a few minutes. At the end of compilation, the files resnet-50_compiled-0000.params and resnet-50_compiled-symbol.json will be created in local directory.

To check the supported operations for the uncompiled model or information on Neuron subgraphs for the compiled model, please see Neuron Check Model.

[ ]:
```
import os
import mxnet as mx
import mx_neuron as neuron
import numpy as np

path='http://data.mxnet.io/models/imagenet/'
mx.test_utils.download(path+'resnet/50-layers/resnet-50-0000.params')
mx.test_utils.download(path+'resnet/50-layers/resnet-50-symbol.json')
block = mx.gluon.nn.SymbolBlock.imports('resnet-50-symbol.json',\
    ['data', 'softmax_label'], 'resnet-50-0000.params', ctx=mx.cpu())

block.hybridize()

# Compile for Inferentia using Neuron
inputs = { "data" : mx.nd.ones([1,3,224,224], name='data', dtype='float32'), 'softmax_
↪label' : mx.nd.ones([1], name='data', dtype='float32') }
block = neuron.compile(block, inputs=inputs)

#save compiled model
block.export("resnet-50_compiled", 0, block)
```

[ ]:
```
!ls
```

10.8 Deploy

Deply on Infenrentia to see the inference results as below:

```
probability=0.643591, class=n02123045 tabby, tabby cat
probability=0.184392, class=n02123159 tiger cat
probability=0.105063, class=n02124075 Egyptian cat
probability=0.030101, class=n02127052 lynx, catamount
probability=0.016112, class=n02129604 tiger, Panthera tigris
```

[ ]:
```
import numpy as np
import mxnet as mx
import mx_neuron as neuron

path='http://data.mxnet.io/models/imagenet/'
mx.test_utils.download(path+'synset.txt')

fname = mx.test_utils.download('https://raw.githubusercontent.com/awslabs/mxnet-model-
↪server/master/docs/images/kitten_small.jpg?raw=true')
img = mx.image.imread(fname)# convert into format (batch, RGB, width, height)
img = mx.image.imresize(img, 224, 224) # resize
img = img.transpose((2, 0, 1)) # Channel first
img = img.expand_dims(axis=0) # batchify
img = img.astype(dtype='float32')

block = mx.gluon.nn.SymbolBlock.imports('resnet-50_compiled-symbol.json',\
    ['data', 'softmax_label'], 'resnet-50_compiled-0000.params', ctx=mx.cpu())
softmax = mx.nd.random_normal(shape=(1,))

out = block(img, softmax).asnumpy()

with open('synset.txt', 'r') as f:
    labels = [l.rstrip() for l in f]

out = block(img, softmax).asnumpy()

prob = np.squeeze(out)
a = np.argsort(prob)[::-1]
for i in a[0:5]:
    print('probability=%f, class=%s' %(prob[i], labels[i]))
```

Natural Language Processing (NLP) Tutorials

- MXNet 1.8: Using data parallel mode tutorial *[html]* [notebook]

10.9 Using Data Parallel Mode with Gluon MXNet

In this tutorial, you will compile a Gluon BERT model and run in data-parallel mode to completely utilize the NeuronCores. Here you will benchmark a multi-worker setup and compare it with a single worker.

This tutorial is intended only for MXNet-1.8.

In this tutorial, we will be using an inf1.2xlarge with the latest AWS Deep Learning AMI (DLAMI). The inf1.2xlarge instance has 1 AWS Inferentia Chip with 4 NeuronCores.

10.9.1 Setting up your environment

To run this tutorial, please make sure you deactivate any existing MXNet conda environments you already using. Install MXNet 1.8 by following the instructions at MXNet Setup Guide. You would also need to change your kernel to use the correct Python environment setup earlier by clicking Kerenel->Change Kernel->Python (Neuron MXNet)

10.9.2 Install dependencies

We have to install gluon-nlp to get the BERT model. Run the following command to install:

[ ]:
```
!python -m pip install gluonnlp
```

10.9.3 Compiling BERT Model

Next, we compile the Gluon BERT model and save it. Once the model is compiled, we use the same model across the entire tutorial. In this tutorial, we will be using a BERT model with sequence length 32

[ ]:
```
import os
import mxnet as mx
import mx_neuron
import gluonnlp as nlp
```

[ ]:
```
BERT_MODEL = 'bert_12_768_12'
BERT_DATA = 'book_corpus_wiki_en_uncased'
batch_size = 1
seq_len = 32
num_cores = 1
dtype = 'float32'

compiled_model_path = '{}.compiled.{}.{}'.format(BERT_MODEL, batch_size, seq_len)

model, vocab = nlp.model.get_model(BERT_MODEL,
                                   dataset_name=BERT_DATA,
                                   use_classifier=False,
                                   use_decoder=False, ctx=mx.cpu())
```

(continues on next page)

(continued from previous page)

```
# Create sample inputs for compilation
words = mx.nd.ones([batch_size, seq_len], name='words', dtype=dtype)
valid_len = mx.nd.ones([batch_size,], name='valid_len', dtype=dtype)
segments = mx.nd.ones([batch_size, seq_len], name='segments', dtype=dtype)
inputs = {'data0': words, 'data1': segments, 'data2': valid_len}

# Compiler Args ~~
options = {}
embeddingNames = ['bertmodel0_word_embed_embedding0_fwd', 'bertmodel0_token_type_embed_
↪embedding0_fwd', 'bertencoder0_embedding0']
options.update({'force_incl_node_names': embeddingNames})
options.update({'flags': ['--fp32-cast matmult']})

# Compile and save ~~
model = mx_neuron.compile(model, inputs=inputs, **options)
model.export(compiled_model_path)
```

10.9.4 Data Parallel Mode

Data Parallel Mode is a setup in which you launch multiple copies of the same model, such that each model is running independently of the other. In other words, each model has its own resources to run inference.

On an inf1.2xlarge instance, we have 4 NeuronCores. Hence, we can launch 4 models such that each model is loaded on a single NeuronCore. This unables us to process 4 request concurrently without linear increase in latency. As a result, the throughput of the system increases when compared to a single model inference. This would also allow us to utilize all the 4 NeuronCores on the instance.

Run through the next set of cells to see the difference in throughput as we scale from one model to 4 models running in parallel.

[ ]:
```
import numpy as np

def get_sample_inputs(batch_size, seq_len):
    words = np.ones([batch_size, seq_len], dtype=np.float32)
    valid_len = np.ones([batch_size,], dtype=np.float32)
    segments = np.ones([batch_size, seq_len], dtype=np.float32)
    inputs = {'data0': words, 'data1': segments, 'data2': valid_len}
    return inputs
```

Next for comparison purposes, we run the setup with 1 worker. To do this, we set the num_cores=1. This would launch only 1 model running on a single NeuronCore. After running the below cell, note down the latency and throughput for the system

[ ]:
```
from parallel import NeuronSimpleDataParallel
from benchmark_utils import Results
import time
import functools
import os
import numpy as np
import warnings
```

(continues on next page)

(continued from previous page)

```
num_cores = 1
batch_size=1

# Each worker process should use one core, hence we set
#    os.environ['NEURON_RT_NUM_CORES'] = "1"
os.environ["NEURON_RT_NUM_CORES"] = "1"

#Result aggregation class (code in bert_benchmark_utils.py)
results = Results(batch_size, num_cores)
def result_handler(output, start, end):
    elapsed = end - start
    results.add_result([elapsed], [end], [start])

inputs = get_sample_inputs(batch_size, seq_len)
parallel_neuron_model = NeuronSimpleDataParallel(compiled_model_path, num_cores, inputs)

#Starting the inference threads
parallel_neuron_model.start_continuous_inference()

# Warm up the cores
for _ in range(num_cores*4):
    parallel_neuron_model.warmup(inputs)

# Need to run for high number of iterations to benchmark the models
for _ in range(1000):
    parallel_neuron_model.infer(inputs)
    # Passing the result_handler as a callback function
    parallel_neuron_model.add_result(result_handler)

# Stop inference
parallel_neuron_model.stop()
# Since we are using a multi-process execution with a shared queue, some inferences
# may still be in execution phase. Hence we need to wait till all the inputs are␣
↪processed
# add_all_results() will collect all the results of requests which are in this state
parallel_neuron_model.add_all_results(result_handler)

with open("benchmark.txt", "w") as f:
    results.report(f, window_size=1)

with open("benchmark.txt", "r") as f:
    for line in f:
        print(line)
```

Now we run the setup with 4 workers. To do this, we set the num_cores=4. This would launch 4 model running each running on individual NeuronCore. All the 4 models are running in individual processes, in other words the models are running in parallel.

To feed the models efficiently, we use the producer-consumer setup, in which all processes running a model act as consumers. All consumers are fed using a sharing input queue.

Now we run the below setup. You may notice, that the throughput increase by >2x when compared to a single worker setup.

[ ]:
```
from parallel import NeuronSimpleDataParallel
from benchmark_utils import Results
import time
import functools
import os
import numpy as np

num_cores = 4
batch_size=1

os.environ["NEURON_RT_NUM_CORES"] = "1"

#Result aggregation class (code in bert_benchmark_utils.py)
results = Results(batch_size, num_cores)
def result_handler(output, start, end):
    elapsed = end - start
    results.add_result([elapsed], [end], [start])

inputs = get_sample_inputs(batch_size, seq_len)
parallel_neuron_model = NeuronSimpleDataParallel(compiled_model_path, num_cores, inputs)

#Starting the inference threads
parallel_neuron_model.start_continuous_inference()

# Warm up the cores
for _ in range(num_cores*4):
    parallel_neuron_model.warmup(inputs)

# Need to run for high number of iterations to benchmark the models
for _ in range(5000):
    parallel_neuron_model.infer(inputs)
    # Passing the result_handler as a callback function
    parallel_neuron_model.add_result(result_handler)

# Stop inference
parallel_neuron_model.stop()
# Since we are using a multi-process execution with a shared queue, some inferences
# may still be in execution phase. Hence we need to wait till all the inputs are␣
↪processed
# add_all_results() will collect all the results of requests which are in this state
parallel_neuron_model.add_all_results(result_handler)

with open("benchmark.txt", "w") as f:
    results.report(f, window_size=1)

with open("benchmark.txt", "r") as f:
    for line in f:
        print(line)
```

Utilizing Neuron Capabilities Tutorials

- NeuronCore Groups tutorial *[html]* [notebook]

10.10 Neuron Apache MXNet (Incubating) - Configurations for NeuronCore Groups Using Resnet50

10.10.1 Introduction:

In this tutorial we will compile and deploy Resnet-50 model in parallel using the concept of NeuronCore Groups on an Inf1 instance. This Jupyter notebook should be run on an instance which is inf1.6xlarge or larger. For simplicity we will run this tutorial on inf1.6xlarge but in real life scenario the compilation should be done on a compute instance and the deployment on inf1 instance to save costs.

Set environment variable NEURON_RT_NUM_CORES to the total number of Neuron cores that will be utilized. The consecutive NeuronCore groups will be created by Neuron Runtime and place the models to the cores according to the compiled size.

Note that in order to map a model to a group, the model must be compiled to fit within the group size. To limit the number of NeuronCores during compilation, use compiler_args dictionary with field "–neuroncore-pipeline-cores" set to the group size. For exmaple, if NEURON_RT_NUM_CORES=4 and two models compiled with "–neuroncore-pipeline-cores=3" and "–neuroncore-pipeline-cores=1" were loaded, the first model would occupy NC0-2 and the second model would occupy NC3.

```
compile_args = {'--neuroncore-pipeline-cores' : 2}
sym, args, auxs = neuron.compile(sym, args, auxs, inputs, **compile_args)
```

In this tutorial we provide two main sections:

1. Compile the Resnet50 model for Neuron
2. Run inference using NeuronCore Groups

Please use environment `conda_aws_neuron_mxnet_p36`.

10.10.2 Compile model for Neuron

Model must be compiled to Inferentia target before it can be used on Inferentia. In the following we will compile the the flag, –neuroncore-pipeline-cores set to 2 and run it. The files resnet-50_compiled-0000.params and resnet-50_compiled-symbol.json will be created in local directory

[ ]:
```
from packaging import version
import mxnet as mx
import numpy as np

import mx_neuron as neuron

path='http://data.mxnet.io/models/imagenet/'
mx.test_utils.download(path+'resnet/50-layers/resnet-50-0000.params')
mx.test_utils.download(path+'resnet/50-layers/resnet-50-symbol.json')
sym, args, aux = mx.model.load_checkpoint('resnet-50', 0)

# Compile for Inferentia using Neuron, fit to NeuronCore group size of 2
```

(continues on next page)

(continued from previous page)

```
inputs = { "data" : mx.nd.ones([1,3,224,224], name='data', dtype='float32') }
compile_args = {'--neuroncore-pipeline-cores' : 2}
sym, args, aux = neuron.compile(sym, args, aux, inputs, **compile_args)

#save compiled model
mx.model.save_checkpoint("resnet-50_compiled", 0, sym, args, aux)
```

10.10.3 Run inference using NeuronCore Groups

Within the framework, the model can be mapped to specific cores using `ctx=mx.neuron(N)` context where N specifies the index of the Neuron core to deploy. For more information, see https://awsdocs-neuron.readthedocs-hosted.com/en/latest/neuron-guide/appnotes/perf/flex-eg.html .

[ ]:
```
import os
import warnings

mx.test_utils.download(path+'synset.txt')

fname = mx.test_utils.download('https://raw.githubusercontent.com/awslabs/mxnet-model-
↪server/master/docs/images/kitten_small.jpg?raw=true')
img = mx.image.imread(fname) # convert into format (batch, RGB, width, height)
img = mx.image.imresize(img, 224, 224) # resize
img = img.transpose((2, 0, 1)) # Channel first
img = img.expand_dims(axis=0) # batchify
img = img.astype(dtype='float32')

sym, args, aux = mx.model.load_checkpoint('resnet-50_compiled', 0)
softmax = mx.nd.random_normal(shape=(1,))
args['softmax_label'] = softmax
args['data'] = img

os.environ["NEURON_RT_NUM_CORES"] = '4'

# Inferentia context - group index 1 (size 2) would skip NC0 and place the
# compiled model onto NC1,2
ctx = mx.neuron(1)

exe = sym.bind(ctx=ctx, args=args, aux_states=aux, grad_req='null')

with open('synset.txt', 'r') as f:
     labels = [l.rstrip() for l in f]

exe.forward(data=img)
prob = exe.outputs[0].asnumpy()# print the top-5
prob = np.squeeze(prob)
a = np.argsort(prob)[::-1]
for i in a[0:5]:
     print('probability=%f, class=%s' %(prob[i], labels[i]))
```

You can experiment with different Neuron core group combinations and different models.

Troubleshooting

If not enough NeuronCores are provided, an error message will be displayed:

```
mxnet.base.MXNetError: [04:01:39] src/operator/subgraph/neuron/./neuron_util.h:541:␣
↪Check failed: rsp.status().code() == 0: Failed load model with Neuron-RTD Error.␣
↪Neuron-RTD Status Code: 9, details: ""
```

Note: To use Jupyter Notebook see:

- running-jupyter-notebook-as-script

API Reference Guide

This document is relevant for: `Inf1`

10.11 Neuron Apache MXNet (Incubating) Compilation Python API

The MXNet-Neuron compilation Python API provides a method to compile model graph for execution on Inferentia.

10.11.1 Description

Within the graph or subgraph, the compile method selects and sends Neuron-supported operations to Neuron-Compiler for compilation and saves the compiled artifacts in the graph. Uncompilable operations are kept as original operations for framework execution.

The compiled graph can be saved using the MXNet save_checkpoint and served using MXNet Model Serving. Please see *Tutorial: Neuron Apache MXNet (Incubating) Model Serving* for more information about exporting to saved model and serving using MXNet Model Serving.

Options can be passed to Neuron compiler via the compile function. For example, the "`--neuroncore-pipeline-cores`" option directs Neuron compiler to compile each subgraph to fit in the specified number of NeuronCores. This number can be less than the total available NeuronCores on an Inf1 instance. See *Neuron compiler CLI Reference Guide (neuron-cc)* for more information about compiler options.

For debugging compilation, use SUBGRAPH_INFO=1 environment setting before calling the compilation script. The extract subgraphs are preserved as hidden files in the run directory. For more information, see *Using Neuron GatherInfo Tool to collect debug and support information*

10.11.2 MXNet 1.5

10.11.3 Method

```
from mxnet.contrib import neuron
neuron.compile(sym, args, aux, inputs, **compile_args)
```

10.11.4 Arguments

- **sym** - Symbol object loaded from symbol.json file
- **args** - args/params dictionary loaded from params file
- **aux** - aux/params dictionary loaded from params file
- **inputs** - a dictionary with key/value mappings for input name to input numpy arrays
- **kwargs** (optional) - a dictionary with key/value mappings for MXNet-Neuron compilation and Neuron Compiler options.
  - For example, to limit the number of NeuronCores per subgraph, use `compile_args={'--neuroncore-pipeline-cores' : N}` where N is an integer representing the maximum number of NeuronCores per subgraph.
  - Additional compiler flags can be passed using `'flags' : [<flags>]` where is a comma separated list of strings. See *Using Neuron GatherInfo Tool to collect debug and support information* for example of passing debug flags to compiler.
  - Advanced option to exclude node names: `compile_args={'excl_node_names' : [<node names>]}` where is a comma separated list of node name strings.

10.11.5 Returns

- **sym** - new partitioned symbol
- **args** - modified args/params
- **auxs** - modified aux/params

10.11.6 Example Usage: Compilation

The following is an example usage of the compilation, with default compilation arguments:

```
from mxnet.contrib import neuron
...
neuron.compile(sym, args, aux, inputs={'data' : img})
```

10.11.7 MXNet 1.8

10.11.8 Method

```
import mx_neuron as neuron
neuron.compile(obj, args=None, aux=None, inputs=None, **compile_args)
```

10.11.9 Arguments

- **obj** - Symbol object loaded from symbol.json file or gluon.HybridBlock object
- **args** (optional) - args/params dictionary loaded from params file. Only needed in case of Symbol object
- **aux** (optional) - aux/params dictionary loaded from params file. Only needed in case of Symbol object
- **inputs** - a dictionary with key/value mappings for input name to input numpy arrays.
- **kwargs** (optional) - a dictionary with key/value mappings for MXNet-Neuron compilation and Neuron Compiler options.
  - For example, to limit the number of NeuronCores per subgraph, use `compile_args={'--neuroncore-pipeline-cores' : N}` where N is an integer representing the maximum number of NeuronCores per subgraph.
  - Additional compiler flags can be passed using `'flags' : [<flags>]` where is a comma separated list of strings. See *Using Neuron GatherInfo Tool to collect debug and support information* for example of passing debug flags to compiler.
  - Advanced option to exclude node names: `compile_args={'excl_node_names' : [<node names>]}` where is a comma separated list of node name strings.
  - work_dir: relative or absolute path for storing compiler artifacts (including params and jsons) generated during compilation when SUBGRAPH_INFO=1.

10.11.10 Returns

- **(sym, args, auxs)** - for symbol object as input. sym, args and auxs are new partitioned symbol, modified args/params and modified aux/params repectively.
- **(obj)** - for gluon.HybridBlock object as input. obj is the parititioned and optimized gluon.Hybrid block object for Neuron backend.

10.11.11 Example Usage: Compilation

The following is an example usage of the compilation, with default compilation arguments for symbol object:

```
import mx_neuron as neuron
...
neuron.compile(sym, args, aux, inputs={'data' : img})
```

The following is an example usage of the compilation, with default compilation arguments for gluon.HybridBlock object (only supported in MXNet-Neuron 1.8):

```
import mx_neuron as neuron
...
neuron.compile(obj, inputs={'data' : img})
```

10.11.12 Example Usage: Extract Compilation Statistics

To extract operation counts, insert the following code after compile step (assume csym is the compiled MXNet symbol):

```
import json

# Return list of nodes from MXNet symbol
def sym_nodes(sym):
  return json.loads(sym.tojson())['nodes']

# Return number of operations in node list
def count_ops(graph_nodes):
  return len([x['op'] for x in graph_nodes if x['op'] != 'null'])

# Return triplet of compile statistics
# - count of operations in symbol database
# - number of Neuron subgraphs
# - number of operations compiled to Neuron runtime
def get_compile_stats(sym):
  cnt = count_ops(sym_nodes(sym))
  neuron_subgraph_cnt = 0
  neuron_compiled_cnt = 0
  for g in sym_nodes(sym):
    if g['op'] == '_neuron_subgraph_op':
      neuron_subgraph_cnt += 1
      for sg in g['subgraphs']:
        neuron_compiled_cnt += count_ops(sg['nodes'])
  return (cnt, neuron_subgraph_cnt, neuron_compiled_cnt)

original_cnt = count_ops(sym_nodes(sym))
post_compile_cnt, neuron_subgraph_cnt, neuron_compiled_cnt = get_compile_stats(csym)
print("INFO:mxnet: Number of operations in original model: ", original_cnt)
print("INFO:mxnet: Number of operations in compiled model: ", post_compile_cnt)
print("INFO:mxnet: Number of Neuron subgraphs in compiled model: ", neuron_subgraph_cnt)
print("INFO:mxnet: Number of operations placed on Neuron runtime: ", neuron_compiled_cnt)
```

```
INFO:mxnet: Number of operations in original model:  67
INFO:mxnet: Number of operations in compiled model:  4
INFO:mxnet: Number of Neuron subgraphs in compiled model:  2
INFO:mxnet: Number of operations placed on Neuron runtime:  65
```

Developer Guide

This document is relevant for: `Inf1`, `Trn1`

10.12 Flexible Execution Group (FlexEG) in Neuron-MXNet

10.12.1 Introduction

Inf1 instances are available with a different number of Inferentia chips, each Inferentia chip is combined of 4 NeuronCores and an Inf1 instance includes 4 to 64 NeuronCores depending on the instance size. With Neuron Runtime 1.x (neuron-rtd server), NeuronCores could be combined into NeuronCore Groups (NCG), which were basic scheduling units of compiled neural network in Neuron. Creation of desired sized NCGs was done at the start of the application and could not be modified afterwards.

Starting with Neuron SDK 1.16.0, and with the introduction of Neuron Runtime 2.x, MXNet Neuron 1.8 introduces Flexible Execution Groups (FlexEG) feature. With FlexEG, you do not have to create NCGs at the start of the process, instead you will set the index of the first NeuronCore you want to load models onto, and FlexEG feature will enable the flexibility of loading models onto any available NeuronCore on the inf1 instance starting from the first NeuronCore you set. This guide will show you how to efficiently utilize NeuronCores using FlexEG feature in NeuronMXNet.

10.12.2 FlexEG

With the introduction of FlexEG, you don't need to create NCGs and can load models onto a group of consecutive NeuronCores by providing the index of the first NeuronCore in the group. Neuron runtime takes care of figuring out the number of NeuronCores required for the given compiled model and loads the model using the required number of cores (sequentially starting with the NeuronCore index provided by the user).

For example, assuming that you have an Inf1.6xl machine and there are 4 models A, B, C, D compiled to 2, 4, 3, and 4 NeuronCores respectively, you can map any model to any core by context `mx.neuron(neuron_core_index)` where `neuron_core_index` is the NeuronCore index (0,1,2,3,4 …).

In the example below, you map model A to `mx.neuron(0)` context, model B to `mx.neuron(2)` context, model C to `mx.neuron(6)` context and model D to `mx.neuron(9)` context.

The above configuration is achieved by using application code similar to below:

```
# Load models (MXNet)
# loaded into the 2 cores starting with core 0
sym, args, aux = mx.model.load_checkpoint(mx_model0_file, 0)
model0 = sym.bind(ctx=mx.neuron(0), args=args, aux_states=aux, grad_req='null')
# loaded into the 4 cores starting with core 2
sym, args, aux = mx.model.load_checkpoint(mx_model1_file, 0)
model1 = sym.bind(ctx=mx.neuron(2), args=args, aux_states=aux, grad_req='null')
# loaded into the 3 cores starting with core 6
sym, args, aux = mx.model.load_checkpoint(mx_model2_file, 0)
model2 = sym.bind(ctx=mx.neuron(6), args=args, aux_states=aux, grad_req='null')
# loaded into the 4 cores starting with core 9
sym, args, aux = mx.model.load_checkpoint(mx_model3_file, 0)
model3 = sym.bind(ctx=mx.neuron(9), args=args, aux_states=aux, grad_req='null')

# run inference by simply calling the loaded model
results0 = model0.forward(data=inputs0)
results1 = model1.forward(data=inputs1)
results2 = model2.forward(data=inputs2)
results3 = model3.forward(data=inputs3)
```

Since there is no NCG creation at the start of the process, you can load the same four models but in a different configuration by changing the context being used for inference. For example, you could map model C to `mx.neuron(0)` context, model A to `mx.neuron(3)` context, model D to `mx.neuron(5)` context and model B to `mx.neuron(9)` context.

10.12.3 Migration from NeuronCore Groups to FlexEG

NeuronCore Groups are defined by setting the environment variable `NEURONCORE_GROUP_SIZES` with a comma separated list of number of cores in each group. In this mode of operation, number of devices (defined in `NEURONCORE_GROUP_SIZES`) are grouped together to create a single entity.

`NEURONCORE_GROUP_SIZES` environment variable is set at runtime:

```
#!/bin/bash
export NEURONCORE_GROUP_SIZES=2,4,3,4
python your_neuron_application.py
```

NeuronCore groups are created once at the start of the application and cannot be modified / re-created till the application process runs. The above flow creates 4 neuron devices with 2,4,3 and 4 devices each. In order to get the same

configuration as the example from before , you map model A to `mx.neuron(0)` context, model B to `mx.neuron(1)` context, model C to `mx.neuron(2)` context and model D to `mx.neuron(3)` context.

This can be achieved programmatically as shown below:

```
# Set Environment
os.environ['NEURONCORE_GROUP_SIZES']='2,4,3,4'

# Load models (MXNet)
# loaded into the first group of NC0-NC1
sym, args, aux = mx.model.load_checkpoint(mx_model0_file, 0)
model0 = sym.bind(ctx=mx.neuron(0), args=args, aux_states=aux, grad_req='null')
# loaded into the second group of NC2-NC5
sym, args, aux = mx.model.load_checkpoint(mx_model1_file, 0)
model1 = sym.bind(ctx=mx.neuron(1), args=args, aux_states=aux, grad_req='null')
# loaded into the third group of NC6-NC8
sym, args, aux = mx.model.load_checkpoint(mx_model2_file, 0)
model2 = sym.bind(ctx=mx.neuron(2), args=args, aux_states=aux, grad_req='null')
# loaded into the fourth group of NC9-NC12
sym, args, aux = mx.model.load_checkpoint(mx_model3_file, 0)
model3 = sym.bind(ctx=mx.neuron(3), args=args, aux_states=aux, grad_req='null')

# run inference by simply calling the loaded model
results0 = model0.forward(data=inputs0)
results1 = model1.forward(data=inputs1)
results2 = model2.forward(data=inputs2)
results3 = model3.forward(data=inputs3)
```

So comparing to FlexEG, we see that in case of NCGs neuron context requires the index of the execution group, while in FlexEG neuron context requires the NeuronCore index of the first NeuronCore on which the model is supposed to be loaded and executed. For example, with `NEURONCORE_GROUP_SIZES='2,4,3,4'`, `ctx=mx.neuron(1)` loads the model on execution group 1 which effectively loads the model on the 2nd NCG group which has 4 NeuronCores.

10.12.4 Best practices when using FlexEG

FlexEG gives the user most flexibility in terms of accessing cores and loading models on specific cores. With this the users can effortlessly load and execute new models on NeuronCores without closing the application. Here we shall outline some of the best practices that should be kept in mind while using FlexEG.

Choosing starting core

FlexEG tries to use the required number of cores (based on the input model) starting with the core index provided by the user. Incase the system, doesnt have the required number of cores after the starting core index, model load will fail. For example: We have a model X which needs 2 cores and an inf1.xl machine with 4 NeuronCores (NeuronCore indexes are: 0, 1, 2 and 3). As the model needs at least 2 cores, valid start indexes for this model are: 0, 1, 2. However if the user gives 3 as the neuron context, then there are no 2 cores available starting from core 3. So it will fail.

Performance vs. Flexibility tradeoff

While using data parallel model of operation (were models are executed in parallel), for optimal performance the user should make sure that the models are not sharing any cores. That is because NeuronCores can execute one model at a time, when two or more models are executed on the same core (assuming that they are already loaded), it executes the first model, stops it, starts the second model and then executes it. This is called model switching and involves additional overhead and prevents execution on model in parallel. For example: assuming that you have an Inf1.6xl machine and there are 4 models A, B, C, D compiled to 2, 4, 3, and 4 NeuronCores respectively. Loading model A to `mx.neuron(0)` context, model B to `mx.neuron(2)` context, model C to `mx.neuron(6)` context and model D to `mx.neuron(9)` context is a good configuration because no two models are sharing NeuronCores and thus can be executed in parallel. However, Loading model A to `mx.neuron(0)` context, model B to `mx.neuron(2)` context, model C to `mx.neuron(5)` context and model D to `mx.neuron(9)` context is a not a good configuration as models B and C share NeuronCore 5 and thus cannot be executed in parallel.

  - *MMS throws a "mxnet.base.MXNetError: array::at" error*
  - *MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded*
  - *Pipeline mode is not able to execute inferences requests in parallel*
  - *Features only in MXNet-Neuron 1.5*
  - *Features only in MXNet-Neuron 1.8*

10.13.1 Inference Runtime Error

Out-of-memory error when calling Symbol API bind() too many times

Important: `NEURONCORE_GROUP_SIZES` will no longer be supported starting Neuron 1.19.0 release if your application is using `NEURONCORE_GROUP_SIZES` please see *Migrate your application to Neuron Runtime 2.x (libnrt.so)* and eol-ncgs-env_2 for more details.

If you see out-of-memory error when using Symbol API's bind() function, please ensure that the bind() function is called once for each desired model instance. For example, on inf1.xlarge, use Symbol API to create 4 parallel instances of a model that was compiled to 1 NeuronCore (–neuroncore-pipeline-cores=1), each is bound to an different mx.neuron(i) context where i is the NeuronCore Group index ranging from 0 to 3. Then use 4 threads to feed the 4 instances in parallel. For example:

```
NUM_PARALLEL = 4
os.environ['NEURONCORE_GROUP_SIZES'] = ','.join('1' for _ in range(NUM_PARALLEL))

data_iter = []
for i in range(NUM_PARALLEL):
    data_iter.append(mx.io.ImageRecordIter(
        path_imgrec=recfile_base, data_shape=(3, 224, 224), batch_size=1,
        prefetch_buffer=1,
        num_parts=NUM_PARALLEL, part_index=i))
```

(continues on next page)

(continued from previous page)

```
sym, args, auxs = mx.model.load_checkpoint('resnet-50_compiled', 0)

exec_list = []
for i in range(NUM_PARALLEL):
    exec = sym.bind(ctx=mx.neuron(i), args=args, aux_states=auxs, grad_req='null')
    exec_list.append(exec)

def single_thread_infer(i):
    for batch in data_iter[i]:
        img = batch.data[0]
        label = batch.label
        feed_dict = {'data': img}
        exe = exec_list[i]
        exe.copy_params_from(feed_dict)
        exe.forward()
        out = exe.outputs[0]

future_list = []
with futures.ThreadPoolExecutor(max_workers=NUM_PARALLEL) as executor:
    for i in range(NUM_PARALLEL):
        future_list.append(executor.submit(single_thread_infer, i))
```

Inference crashed with MXNetError: InferShapeKeyword argument name xyz not found

If you see MXNetError:

```
mxnet.base.MXNetError: [11:55:39] src/c_api/c_api_symbolic.cc:508: InferShapeKeyword␣
↪argument name xyz not found."
```

This is followed by a list of "Candidate arguments". This list shows all the input argument names that the model knows about, and 'xyz' is not in the list. To fix this, remove entry xyz from the feed dictionary.

Inference crashed at mx.nd.waitall() with MXNetError: Check failed: bin.dtype() == mshadow::kUint8

When executing Symbol API's forward function followed by mx.nd.waitall(), where MXNetError exception occurs with 'Check failed: bin.dtype() == mshadow::kUint8'.

Inference crashed with NRTD error 1002

During inference, the user may encounter an error with details "[NRTD:infer_wait] error: 1002":

```
mxnet.base.MXNetError: [11:26:56] src/operator/subgraph/neuron/./neuron_util.h:1175:␣
↪Check failed: rsp_wait.status().code() == 0 || rsp_wait.status().code() == 1003: Failed
Infer Wait with Neuron-RTD Error. Neuron-RTD Status Code: 1002, details: "[NRTD:infer_
↪wait] error: 1002
"
```

Runtime errors are listed in rtd-return-codes. In particular, 1002 means that some invalid input has been submitted to infer, e.g. missing some of the input tensors, incorrect input tensor sizes. Please examine /var/log/syslog to see imore details on the error. For example, you may see:

```
Oct 30 19:13:39 ip-172-31-93-131 nrtd[1125]: [TDRV:io_queue_prepare_input_nonhugetlb]␣
↪Unexpected input size, for data00, expected: 2097152, received: 33554432
```

This means that the input tensor size is larger than what the model was compiled for (i.e. the example input tensor shapes passed during compilation.

10.13.2 Multi-Model Server

Failed to create NEURONCORE Group with GRPC Error. Status Error: 14, Error message: "Connect Failed"

NOTE: This error only applies to MXNet 1.5.

If the client is unable to start workers and you get a message that MMS is unable to create NeuronCore Group, please check that Neuron RTD is running (neuron-rtd process).

```
{
"code": 500,
"type": "InternalServerException",
"message": "Failed to start workers"
}
```

```
2019-10-23 19:56:23,187 [INFO ] W-9000-squeezenet_v1.1_compiled-stdout com.amazonaws.ml.
↪mms.wlm.WorkerLifeCycle - [19:56:23] src/operator/subgraph/inferentia/./inferentia_
↪util.h:218: Check failed: status.ok() Failed to create NeuronCore Group with GRPC␣
↪Error. Status Error: 14, Error message: "Connect Failed"
```

Multiple MMS workers die with "Backend worker process die." message

Important: NEURONCORE_GROUP_SIZES will no longer be supported starting Neuron 1.19.0 release if your application is using NEURONCORE_GROUP_SIZES please see *Migrate your application to Neuron Runtime 2.x (libnrt.so)* and eol-ncgs-env_2 for more details.

If you run inference with MMS and get multiple messages "Backend worker process die", please ensure that the number of workers ("intial_workers") passed during load model is less than or equal to number of NeuronCores available divided by number of NeuronCores required by model.

```
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - Backend worker process die.
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - Traceback (most recent call last):
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - File "/usr/local/lib/python3.6/site-packages/
↪mxnet/symbol/symbol.py", line 1524, in simple_bind
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - ctypes.byref(exe_handle)))
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - File "/usr/local/lib/python3.6/site-packages/
↪mxnet/base.py", line 252, in check_call
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - raise MXNetError(py_str(_LIB.
↪MXGetLastError()))
com.amazonaws.ml.mms.wlm.WorkerLifeCycle - mxnet.base.MXNetError: [00:26:32] src/
↪operator/subgraph/neuron/./neuron_util.h:221: Check failed: 0 == create_eg_rsp.
↪status().code() Failed to create NeuronCore Group with KRTD Error. KRTD Status Code: 4,
↪ details: ""
```

As indicated in *Performance Tuning*, for greater flexibility user can use NEURONCORE_GROUP_SIZES to specify the groupings of NeuronCores into Neuron devices, each device consisting of one or more NeuronCores. Each worker would take a device. The total number of NeuronCores taken by all the workers should be less than or equal the total number of NeuronCores visible to neuron-rtd. This situation should be considered at full load (MMS scales up to max_workers). Additionally, to properly assign model to Neuron device, the environment NEURONCORE_GROUP_SIZES must be specified within the model server class (ie. mxnet_model_service.py in the example above). For example, add the following line within mxnet_model_service.py for model compiled to 1 NeuronCore:

```
os.environ['NEURONCORE_GROUP_SIZES'] = '1'
```

More information about max_worker limit setting can be found at MMS Management API Documentation. For example, to run up to 4 workers in inf1.xlarge where 4 NeuronCores are available by default to Neuron-RTD, set max_workers to 4:

```
curl -v -X PUT "http://localhost:8081/models/squeezenet_v1.1_compiled?min_worker=1?max_
↪worker=4"
```

MMS throws a "mxnet.base.MXNetError: array::at" error

If you see "mxnet.base.MXNetError: array::at" when running MMS please check that NDArray/Gluon API is not used as they are not supported in MXNet-Neuron. If you would like to use NDArray or Gluon API, please upgrade to MXNet 1.8.

MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded

NOTE: This issue is resolved in version 1.5.1.1.1.88.0 released 11/17/2020 and only applies for MXNet 1.5.

MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded (deleted) from model server. Restarting the model server may fail with "Failed to create NEURONCORE_GROUP" error:

```
mxnet.base.MXNetError: [00:26:59] src/operator/subgraph/neuron/./neuron_util.h:348:␣
↪Check failed:    0 == create_eg_rsp.status().code(): Failed to create NEURONCORE_GROUP␣
↪with Neuron-RTD Error. Neuron-RTD Status Code: 9, details: ""
```

The workaround is to run "*/opt/aws/neuron/bin/neuron-cli reset*" to clear Neuron RTD states after all models are unloaded and server is shut down before restarting the model server.

Pipeline mode is not able to execute inferences requests in parallel

If you see that multiple executors in a neuron pipeline setup (one model compiled for more than one neuron-cores using *–neuroncore-pipeline-cores* option during compilation) are not running in parallel, please set the following MXNet's environment variables before inference to allow mxnet to execute the CPU ops in parallel. Otherwise it will be sequential and stall the executors.

`MXNET_CPU_WORKER_NTHREADS` is used to do that. Setting its value to `__subgraph_opt_neuroncore__` in the compiled model json will ensure that all the executors (threads) can be run in parallel.

Features only in MXNet-Neuron 1.5

- Shared memory for IFMaps transfer to neuron runtime (has higher performance compared to GRPC mode)
- Neuron profiling using MXNet

Features only in MXNet-Neuron 1.8

- Gluon API support
- Library mode neuron runtime

This document lists the release notes for MXNet-Neuron framework.

10.14.1 Apache MXNet Neuron release [1.8.0.2.2.2.0]

Date: 03/25/2022

New in this release

- Added support for unloading models from a NeuronDevice by deleting the model instance in user application. Users can now call `del` in Python on an executor and to unload the model from a NeuronDevice (provided the deleted executor is the last executor pointing to the given model). This requires the latest `aws-mx-1.8` package from `https://aws-mx-pypi.s3.us-west-2.amazonaws.com/1.8.0/aws_mx-1.8.0.2-py2.py3-none-manylinux2014_x86_64.whl`.

Bug fixes

- Fixed a memory leak caused by stale unloaded models in NeuronDevice memory. For this fix to take effect please install aws-mx package from https://aws-mx-pypi.s3.us-west-2.amazonaws.com/1.8.0/aws_mx-1.8.0.2-py2.py3-none-manylinux2014_x86_64.whl along with the latest mx-neuron package.

10.14.2 Apache MXNet Neuron release [1.8.0.2.1.5.0]

Date: 01/20/2022

New in this release

- Added support of `mx_neuron.__version__` to get the build version of MXNet Neuron plugin

Bug fixes

- Fixed assertion errors when inference was completed with NaNs. The expected behavior is to complete inference successfully and warn the user that ``NaN``s were seen during the current inference.
- Fixed compile issue when individual output nodes have multiple output nodes. Because the output index was being dropped, fewer number of output feature maps were being considered and that caused failures during inference.

10.14.3 Apache MXNet Neuron release [1.8.0.2.0.276.0]

Date: 11/05/2021

- Updated Neuron Runtime (which is integrated within this package) to `libnrt 2.2.18.0` to fix a container issue that was preventing the use of containers when /dev/neuron0 was not present. See details here neuron-runtime-release-notes.

10.14.4 Apache MXNet Neuron release [1.8.0.2.0.271.0]

New in this release

- MXNet Neuron 1.8 now support Neuron Runtime 2.x (`libnrt.so` shared library) only.

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.
  - Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

- Introducing Flexible Execution Groups (FlexEG) feature. See *Flexible Execution Group (FlexEG) in Neuron-MXNet* application note.

Resolved Issues

- Fixed a bug that prevented compilation of gluon models with multiple cpu and neuron nodes.
- Added more debug logic to help with profiling of model load timing.

10.14.5 [1.5.1.1.7.0.0]

New in this release

- MXNet 1.5 enters maintenance mode. Please visit maintenance_mxnet_1_5 for more information.

Resolved Issues

- Minor bug fixes.

10.14.6 [1.5.1.1.6.5.0]

Date 08/12/2021

Summary

Minor bug fixes and enhancements for MXNet 1.5 Neuron.

10.14.7 [1.8.0.1.3.4.0]

Date 08/12/2021

Summary

Minor bug fixes and enhancements for MXNet 1.8 Neuron.

10.14.8 [1.5.1.1.6.1.0]

Date 07/02/2021

Summary

Minor bug fixes and enhancements for MXNet 1.5 Neuron.

10.14.9 [1.8.0.1.3.0.0]

Date 07/02/2021

Summary

Support for Autoloop, Cpredict API and minor bug fixes and enhancements for MXNet 1.8 Neuron.

Major New Features

- Added support for Autoloop feature for MXNet 1.8 Neuron.

Resolved Issues

- Added support for CPredict API.

10.14.10 [1.8.0.1.2.1.0]

Date 5/28/2021

Summary

Minor bug fixes and enhancements for MXNet 1.8 Neuron

Resolved Issues

- Added support for Neuron profiler

10.14.11 [1.8.0.1.1.2.0]

Date 4/30/2021

Summary

Initial release of Apache MXNet (Incubating) 1.8 for Neuron

Major New Features

- Gluon API and Neuron support for NLP BERT models
- Neuron is now a plugin
- Please note new API changes to support plugin mode: *Neuron Apache MXNet (Incubating) Compilation Python API*

10.14.12 [1.5.1.1.4.x.x]

Date 5/28/2021

Summary

- Minor enhancements.

10.14.13 [1.5.1.1.4.4.0]

Date 4/30/2021

Summary

- Resolve an issue with Neuron profiling.

Resolved Issues

- Issue: when Neuron profiling is enabled in MXNet-Neuron 1.5.1 (using NEURON_PROFILE=<dir>), and TensorBoard is used to read in the profiled data, user would see an error messsage "panic: runtime error: index out of range". This issue is resolved in this release.

10.14.14 [1.5.1.1.3.8.0]

Date 3/4/2021

Summary

Minor enhancements.

10.14.15 [1.5.1.1.3.7.0]

Date 2/24/2021

Summary

Fix for CVE-2021-3177.

10.14.16 [1.5.1.1.3.2.0]

Date 1/30/2021

Summary

Various minor improvements

10.14.17 [1.5.1.1.2.1.0]

Date 12/23/2020

Summary

Various minor improvements

10.14.18 [1.5.1.1.1.88.0]

Date 11/17/2020

Summary

This release includes the bug fix for MXNet Model Server not being able to clean up Neuron RTD states after model is unloaded (deleted) from model server.

Resolved Issues

- Issue: MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded (deleted) from model server.
  - Workaround for earlier versions: run "`/opt/aws/neuron/bin/neuron-cli reset`" to

  clear Neuron RTD states after all models are unloaded and server is shut down.

10.14.19 [1.5.1.1.1.52.0]

Date 09/22/2020

Summary

Various minor improvements.

Major New Features

Resolved Issues

- Issue: When first importing MXNet into python process and subprocess call is invoked, user may get an OSError exception "OSError: [Errno 14] Bad address" during subprocess call (see https://github.com/apache/incubator-mxnet/issues/13875 for more details). This issue is fixed with a mitigation patch from MXNet for Open-MP fork race conditions.
  - Workaround for earlier versions: Export KMP_INIT_AT_FORK=false before running python process.

10.14.20 [1.5.1.1.1.1.0]

Date 08/08/2020

Summary

Various minor improvements.

Major New Features

Resolved Issues

10.14.21 [1.5.1.1.0.2101.0]

Date 08/05/2020

Summary

Various minor improvements.

Major New Features

Resolved Issues

10.14.22 [1.5.1.1.0.2093.0]

Date 07/16/2020

Summary

This release contains a few bug fixes and user experience improvements.

Major New Features

Resolved Issues

- User can specify NEURONCORE_GROUP_SIZES without brackets (for example, "1,1,1,1"), as can be done in TensorFlow-Neuron and PyTorch-Neuron.
- Fixed a memory leak when inferring neuron subgraph properties
- Fixed a bug dealing with multi-input subgraphs

10.14.23 [1.5.1.1.0.2033.0]

Date 6/11/2020

Summary

- Added support for profiling during inference

Major New Features

- Profiling can now be enabled by specifying the profiling work directory using NEURON_PROFILE environment variable during inference. For an example of using profiling, see tensorboard-neuron. (Note that graph view of MXNet graph is not available via TensorBoard).

Resolved Issues

Known Issues and Limitations

Other Notes

10.14.24 [1.5.1.1.0.1900.0]

Date 5/11/2020

Summary

Improved support for shared-memory communication with Neuron-Runtime.

Major New Features

- Added support for the BERT-Base model (base: L-12 H-768 A-12), max sequence length 64 and batch size of 8.
- Improved security for usage of shared-memory for data transfer between framework and Neuron-Runtime
- Improved allocation and cleanup of shared-memory resource
- Improved container support by automatic falling back to GRPC data transfer if shared-memory cannot be allocated by Neuron-Runtime

Resolved Issues

- User is unable to allocate Neuron-Runtime shared-memory resource when using MXNet-Neuron in a container to communicate with Neuron-Runtime in another container. This is resolved by automatic falling back to GRPC data transfer if shared-memory cannot be allocated by Neuron-Runtime.
- Fixed issue where some large models could not be loaded on inferentia.

Known Issues and Limitations

Other Notes

10.14.25 [1.5.1.1.0.1596.0]

Date 3/26/2020

Summary

No major changes or fixes

Major New Features

Resolved Issues

Known Issues and Limitations

Other Notes

10.14.26 [1.5.1.1.0.1498.0]

Date 2/27/2020

Summary

No major changes or fixes.

Major New Features

Resolved Issues

The issue(s) below are resolved:

- Latest pip version 20.0.1 breaks installation of MXNet-Neuron pip wheel which has py2.py3 in the wheel name.

Known Issues and Limitations

- User is unable to allocate Neuron-Runtime shared-memory resource when using MXNet-Neuron in a container to communicate with Neuron-Runtime in another container. To work-around, please set environment variable NEURON_RTD_USE_SHM to 0.

Other Notes

10.14.27 [1.5.1.1.0.1401.0]

Date 1/27/2020

Summary

No major changes or fixes.

Major New Features

Resolved Issues

- The following issue is resolved when the latest multi-model-server with version >= 1.1.0 is used with MXNet-Neuron. You would still need to use "`/opt/aws/neuron/bin/neuron-cli reset`" to clear all Neuron RTD states after multi-model-server is exited:
  - Issue: MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded (deleted) from model server and previous workaround "`/opt/aws/neuron/bin/neuron-cli reset`" is unable to clear all Neuron RTD states.

Known Issues and Limitations

- Latest pip version 20.0.1 breaks installation of MXNet-Neuron pip wheel which has py2.py3 in the wheel name. This breaks all existing released versions. The error looks like:

```
Looking in indexes: https://pypi.org/simple, https://pip.repos.neuron.amazonaws.com
ERROR: Could not find a version that satisfies the requirement mxnet-neuron (from␣
↪versions: none)
ERROR: No matching distribution found for mxnet-neuron
```

- Work around: install the older version of pip using "pip install pip==19.3.1".

Other Notes

10.14.28 [1.5.1.1.0.1325.0]

Date 12/1/2019

Summary

Major New Features

Resolved Issues

- Issue: Compiler flags cannot be passed to compiler during compile call. The fix: compiler flags can be passed to compiler during compile call using "flags" option followed by a list of flags.
- Issue: Advanced CPU fallback option is a way to attempt to improve the number of operators on Inferentia. The default is currently set to on, which may cause failures. The fix: This option is now off by default.

Known Issues and Limitations

- Issue: MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded (deleted) from model server and previous workaround "`/opt/aws/neuron/bin/neuron-cli reset`" is unable to clear all Neuron RTD states.
  - Workaround: run "`sudo systemctl restart neuron-rtd`" to clear Neuron RTD states after all models are unloaded and server is shut down.

Other Notes

10.14.29 [1.5.1.1.0.1349.0]

Date 12/20/2019

Summary

No major changes or fixes. Released with other Neuron packages.

10.14.30 [1.5.1.1.0.1325.0]

Date 12/1/2019

Other Notes

10.14.31 [1.5.1.1.0.1260.0]

Date: 11/25/2019

Summary

This version is available only in released DLAMI v26.0 and is based on MXNet version 1.5.1. Please dlami-rn-known-issues to latest version.

Major new features

Resolved issues

Known issues and limitations

- Issue: Compiler flags cannot be passed to compiler during compile call.
- Issue: Advanced CPU fallback option is a way to attempt to improve the number of operators on Inferentia. The default is currently set to on, which may cause failures.
  - Workaround: explicitly turn it off by setting compile option op_by_op_compiler_retry to 0.
- Issue: Temporary files are put in current directory when debug is enabled.
  - Workaround: create a separate work directory and run the process from within the work directory
- Issue: MXNet Model Server is not able to clean up Neuron RTD states after model is unloaded (deleted) from model server.
  - Workaround: run "`/opt/aws/neuron/bin/neuron-cli reset`" to clear Neuron RTD states after all models are unloaded and server is shut down.
- Issue: MXNet 1.5.1 may return inconsistent node names for some operators when they are the primary outputs of a Neuron subgraph. This causes failures during inference.
  - Workaround : Use the `excl_node_names` compilation option to change the partitioning of the graph during compile so that these nodes are not the primary output of a neuron subgraph. See *Neuron Apache MXNet (Incubating) Compilation Python API*

```
compile_args = { 'excl_node_names': ["node_name_to_exclude"] }
```

Models Supported

The following models have successfully run on neuron-inferentia systems

1. Resnet50 V1/V2
2. Inception-V2/V3/V4
3. Parallel-WaveNet
4. Tacotron 2
5. WaveRNN

Other Notes

- Python versions supported:
  - 3.5, 3.6, 3.7
- Linux distribution supported:
  - Ubuntu 18, Amazon Linux 2

CHAPTER

ELEVEN

NEURON RUNTIME

Neuron runtime consists of kernel driver and C/C++ libraries which provides APIs to access Inferentia and Trainium Neuron devices. The Neuron ML frameworks plugins for TensorFlow, PyTorch and Apache MXNet use the Neuron runtime to load and run models on the NeuronCores. Neuron runtime loads compiled deep learning models, also referred to as Neuron Executable File Format (NEFF) to the Neuron devices and is optimized for high-throughput and low-latency.

API Reference Guide

This document is relevant for: `Inf1`, `Trn1`

11.1 Neuron Runtime Configuration

Neuron Runtime is responsible for executing ML models on Neuron Devices. Neuron Runtime determines which NeuronCore will execute which model and how to execute it. Configuration of the Neuron Runtime is controlled through the use of Environment variables at the process level. By default, Neuron framework extensions will take care of Neuron Runtime configuration on the user's behalf. Explicit configurations are also possible when attempting to achieve a desired behavior.

This guide provides an overview of the different environment variables available to configure Neuron Runtime behavior.

Table 1: Environment Variables

Name	Description	Type	Expected Values	Default Value
`NEURON_RT_VISIBLE_CORES`	Range of specific NeuronCores needed by the process	Integer range (like 1-3)	Any value or range between 0 to Max NeuronCore in the system.	None
`NEURON_RT_NUM_CORES`	Number of NeuronCores required by the process.	Integer	A value from 1 to Max NeuronCore in the system.	0, which is interpretted as "all"
`NEURON_RT_LOG_LOCATION`	Runtime log location	string	console or syslog	console
`NEURON_RT_LOG_LEVEL`	Runtime log verbose level	string	ERROR, WARNING, INFO, DEBUG, TRACE	ERROR
`NEURON_RT_EXEC_TIMEOUT`	Timeout for execution in seconds	Integer	0 to INT_MAX	30
`NEURON_RT_VALIDATE_NEFF`	Validate NEFF contents before loading into accelerator	Boolean	TRUE or FALSE	FALSE

11.1.1 NeuronCore Allocation

Important: NEURONCORE_GROUP_SIZES is being deprecated, if your application is using NEURONCORE_GROUP_SIZES please see *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for more details.

By default, Neuron Runtime initializes all the cores present in the system and reserves them for the current process.

Note: Once a NeuronCore is reserved for a process, it cannot be used by another process at all, until the process reserving that NeuronCore is terminated.

Using NEURON_RT_VISIBLE_CORES

For parallel processing, NEURON_RT_VISIBLE_CORES can be used to control which NeuronCores each process would reserve. This variable is specified with a single NeuronCore index or an inclusive range value.

For example, if a process (myapp.py) requires one NeuronCore, then it can be started with NEURON_RT_VISIBLE_CORES=0 to limit the process to NeuronCore 0. For parallel processing, multiple process can be started (without any change to myapp.py code) with different NEURON_RT_VISIBLE_CORES values. Here is an example that runs myapp.py on inf1.xlarge in parallel across the four different NeuronCores available in the inf1.xlarge.

```
NEURON_RT_VISIBLE_CORES=0 myapp.py &
NEURON_RT_VISIBLE_CORES=1 myapp.py &
NEURON_RT_VISIBLE_CORES=2 myapp.py &
NEURON_RT_VISIBLE_CORES=3 myapp.py &
```

If myapp.py required 3 NeuronCores and was running on a inf1.6xlarge (16 NeuronCores maximum), the first instance of myapp.py could use NeuronCores 0-2, the next instance could use 3-5 and so on:

```
NEURON_RT_VISIBLE_CORES=0-2 myapp.py &
NEURON_RT_VISIBLE_CORES=3-5 myapp.py &
NEURON_RT_VISIBLE_CORES=6-8 myapp.py &
NEURON_RT_VISIBLE_CORES=9-11 myapp.py &
NEURON_RT_VISIBLE_CORES=12-14 myapp.py &
```

Using NEURON_RT_NUM_CORES

If NEURON_RT_NUM_CORES is set to a value between 1 and the maximum number of NeuronCores in the instance, Neuron Runtime will attempt to automatically reserve the number of free NeuronCores specified for the process. The difference between NEURON_RT_VISIBLE_CORES and NEURON_RT_NUM_CORES is that, NEURON_RT_VISIBLE_CORES specifies exact NeuronCores to allocate where as NEURON_RT_NUM_CORES specifies the number of NeuronCores needed and Neuron Runtime selects free NeuronCores.

Using the same example earlier where myapp.py needed 3 cores, but _which_ 3 cores was of no concern, the same application could be executed in parallel up to 5 times on an inf1.6xlarge (16 NeuronCore max):

```
NEURON_RT_NUM_CORES=3 myapp.py &
NEURON_RT_NUM_CORES=3 myapp.py &
NEURON_RT_NUM_CORES=3 myapp.py &
```

(continues on next page)

(continued from previous page)

```
NEURON_RT_NUM_CORES=3 myapp.py &
NEURON_RT_NUM_CORES=3 myapp.py &
```

Executing a 6th `NEURON_RT_NUM_CORES=3 myapp.py &` in the above example would fail as there is only a single NeuronCore still free.

Notes

1. Number of NeuronCores in a inferentia device is 4
2. Number of inferentia is depends on the instance size.
3. The NeuronCore index in NEURON_RT_VISIBLE_CORES starts from 0 and ends at (number of NeuronDevices * number of NeuronCores) - 1.
4. By default, `NEURON_RT_NUM_CORES` is set to `0`, which indicates to RT that all cores are to be used.
5. NEURON_RT_VISIBLE_CORES takes precedence over NEURON_RT_NUM_CORES. If specified, all cores within the range will be assigned to the owning process.

11.1.2 Logging and debug-ability

By default, Neuron Runtime logs to syslog with verbose level of *INFO* and only *ERROR* s are logged in console. The following code snippet shows ways to increase/decrease the log level.

```
NEURON_RT_LOG_LEVEL=INFO myapp.py         # Sets the log level for syslog and console to␣
↪INFO
NEURON_RT_LOG_LOCATION=console NEURON_RT_LOG_LEVEL=QUIET myapp.py    # Completely␣
↪disables console logging.
```

By default, Neuron Runtime expects the NeuronCore to complete execution of any model with in 2 seconds. If NeuronCore didnt complete the execution within 2 seconds then runtime would fail the execution with timeout error. Most of the models takes few milliseconds to complete so 2 seconds(2000 milliseconds) is more than adequate. However if your model is expected to run more than 2 seconds then you can increase the timeout with NEURON_RT_EXEC_TIMEOUT.

```
NEURON_RT_EXEC_TIMEOUT=5 myapp.py       # increases the timeout to 5 seconds
```

11.1.3 Checksum

To execute a model(NEFF), Neuron Runtime needs to load the NEFF file into NeuronCore and run. Neuron Runtime provides a way to do checksum validation on each NEFF file while loading to validate the file is not corrupted. This option is off by default to avoid performance penalty during model load time(~50%).

```
NEURON_RT_VALIDATE_HASH=true myapp1.py     # enables model checksum validation while␣
↪loading
NEURON_RT_VALIDATE_HASH=false myapp2.py    # disables(default) model checksum validation␣
↪while loading
```

This document is relevant for: `Inf1`, `Trn1`

11.2 Neuron Runtime Troubleshooting on Trn1

Table of contents

- *Memory Errors*
  - *Transient memory errors*
  - *Persistent memory errors*
  - *Failure to initialize Neuron*
  - *An application is trying to use more cores that are available on the instance*
- *EFA and Collective Communication Errors*
  - *Missing aws-neuronx-collectives package*
  - *Missing efa installer package.*
  - *EFA is not enabled in trn1.32xlarage*
  - *Communication timeout*
  - *Communication errors.*
  - *EFA Kernel messages (dmesg) after process termination.*
  - *Failure to find bootstrap interface*
  - *Name resolution failure*

11.2.1 Memory Errors

Transient memory errors

```
Uncorrectable memory error is detected on Neuron device: 5:1 metadata: 0x2. The error␣
↪might cause incorrect computational results and might affect training convergence.␣
↪Please
terminate and restart from the last checkpoint if the convergence is impacted.
```

Solution

Neuron detected a single uncorrectable bit flip in the device memory. The execution can continue but there is a possibility of a numerical error. If this is a concern, terminate and restart from the last known good check point.

Persistent memory errors

```
Uncorrectable memory error is detected on Neuron device: 5:1 metadata: 0x2. Failing␣
↪execution.
```

Solution

Multiple uncorrectable errors are detected during execution. The execution cannot continue. This is most likely caused by faulty hardware. Terminate and move to a different instance.

Failure to initialize Neuron

```
nd0 nc0 Timestamp program stop timeout (1000 ms)
nd0 nc0 Error while waiting for timestamp program to end on TPB eng 0
nd0 nc0 Failed to stop neuron core
nd0 nc0 Failed to end timestamp sync programs
TDRV not initialized
Failed to initialize devices, error:5
```

Solution

Previously executed application left Neuron devices in running state. Reset Neuron devices but reloading Neuron Driver. Note, this is a temporary workaround, future versions of Neuron will reset running devices automatically.

```
sudo rmmod neuron; sudo modprobe neuron
```

An application is trying to use more cores that are available on the instance

```
Could not open the nd1
```

Solution

Use properly sized instance. trn1.32xlarge has 32 Neuron Cores, trn1.2xlarge has 2 Neuron Cores.

11.2.2 EFA and Collective Communication Errors

Missing aws-neuronx-collectives package

aws-neuronx-collectives package is required to execute Collective Communication on a single instance and across multiple instances.

```
NCCL init error: Error opening libnccom.so, cannot use collective operations! Please set␣
↪LD_LIBRARY_PATH to library location. Error: libnccom.so: cannot open shared object
file: No such file or directory
Please make sure to install correct version of aws-neuronx-collectives; for detailed␣
↪installation instructions visit Neuron documentation
```

Solution

Install aws-neuornx-collectives package. If the installation used non-default destination set LD_LIBRARY_PATH.

Missing efa installer package.

efa-installer package is required to execute Collective Communication across multiple instances.

```
Unable to run multi-instance workload.  Ofi plugin is not installed or EFA is not enabled
```

Solution

Follow the directions to install efa-installer package. Make sure to add the path to to libfabric library to LD_LIBRARY_PATH

EFA is not enabled in trn1.32xlarage

EFA is used as a transport for Collective Communication among multiple instances. EFA must be enabled on the instances used for multi-node training.

```
OFI plugin initNet() failed is EFA enabled?
```

Solution

Confirm that EFA is enabled by running lspci command and making sure there are eight EFA devices. For example:

```
[ec2-user@ip-10-0-13-247 ~]$ lspci -tv
-+-[0000:a0]-+-00.0  Amazon.com, Inc. Elastic Network Adapter (ENA)
 |           +-01.0  Amazon.com, Inc. Elastic Network Adapter (ENA)
 |           +-19.0  Amazon.com, Inc. Elastic Fabric Adapter (EFA)

             +-01.0  Intel Corporation 82371SB PIIX3 ISA [Natoma/Triton II]
             +-01.3  Intel Corporation 82371AB/EB/MB PIIX4 ACPI
             +-03.0  Amazon.com, Inc. Device 1111
             +-04.0  Amazon.com, Inc. NVMe EBS Controller
             \-1f.0  Amazon.com, Inc. NVMe EBS Controller
```

Launch instances with EFA enabled and try again. If not planning to use the instances for multi-node training or running on trn1.2xlarge, this error message can be ignored.

Communication timeout

Ranks exchange information during NEFF loading and before the start of the execution. The loading/execution cannot move forward until all ranks are ready.

```
Timeout waiting for RX (waited 120 sec) - retrying
```

```
Timeout waiting for incoming connection (waited 120 sec) - retrying
```

```
Connect to localhost:33666 failed - retrying
```

Solution

The communication timeouts are not fatal. The ranks will continue waiting forever. In most case the timeouts are caused by one of the ranks getting delayed, usually be recompilation of a graph. The execution is resumed after the graph is compiled (might take significant amount of time). It is possible to determine if compilation is in progress by checking the logs on all nodes.

Communication timeouts might also indicate that one of the nodes or ranks is hang. If that is the case, terminate the run and restart from the last known good check point.

Communication errors.

```
RX, connection closed by remote peer
```

There could be other similar messages indicating that ranks failed to communicate.

Solution

One of the ranks or nodes encountered a problem and terminated. Terminate the run and restart from the last known check point.

EFA Kernel messages (dmesg) after process termination.

```
[298850.502143] neuron:npid_detach: neuron:npid_detach: pid=90193, slot=0
[298850.919248] efa 0000:a0:1a.0 rdmap160s26: Failed to process command DEREG_MR (opcode␣
↪8) comp_status 7 err -22
```

Solution

When a process that executed Collective Communication terminates it deregisters buffers that were registered with the networking stack. There is a race condition because the Neuron driver deregisters buffers owned by terminating process as part of the memory cleanup. The error is benign and will be removed in the future releases.

Failure to find bootstrap interface

```
No interface found in the same subnet as remote address fe80::1461:22ff:fe33:b471<45015>
No usable listening interface found
```

Solution

Bootstrap code incorrectly trying to use link-local IPv6 address for communication. This error will be fixed in the next Neuron release. In the meantime, as a workaround, disable IPv6 on the instances.

```
sudo sysctl -w net.ipv6.conf.all.disable_ipv6=1
sudo sysctl -w net.ipv6.conf.default.disable_ipv6=1
```

Name resolution failure

```
WARN Invalid NCCL_COMM_ID [compute1-st-kaena-training-0-1.pcluster-trn1-24-pdx80-2n.
↪pcluster:41211], please use format: <ipv4>:<port> or [<ipv6>]:<port>
```

Solution

Verify that the name can be resolved by DNS by using nslookup or dig. Currently released version fails to resolve FQDN longer than 63 characters. This error will be fixed in the upcoming Neuron release. In the mean time use shorter names to ensure that FQDN length does not exceed the maximum of 63 characters.

This document is relevant for: `Inf1`

11.3 Neuron Runtime Troubleshooting on Inf1

This document aims to provide more information on how to fix issues you might encounter while using the Neuron Runtime 2.x or above. For each issue we will provide an explanation of what happened and what can potentially correct the issue.

If your issue is not listed below or you have a more nuanced problem, contact us via issues posted to this repo, the AWS Neuron developer forum, or through AWS support.

Table of contents

11.3.1 Neuron Driver installation fails

aws-neuron-dkms is a driver package which needs to be compiled during installation. The compilation requires kernel headers for the instance's kernel. `uname -r` can be used to find kernel version in the instance. In some cases, the installed kernel headers might be newer than the instance's kernel itself.

Please look at the aws-neuron-dkms installation log for message like the following:

```
Building for 4.14.193-149.317.amzn2.x86_64
Module build for kernel 4.14.193-149.317.amzn2.x86_64 was skipped since the
kernel headers for this kernel does not seem to be installed.
```

If installation log is not available, check whether the module is loaded.

```
$ lsmod | grep neuron
```

If the above has no output then that means `aws-neuron-dkms` installation is failed.

Solution

1. Stop all applications using the NeuronCores.
2. Uninstall aws-neuron-dkms `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
3. Install kernel headers for the current kernel `sudo apt install -y linux-headers-$(uname -r)` or `sudo yum install -y kernel-devel-$(uname -r) kernel-headers-$(uname -r)`
4. Install aws-neuron-dkms `sudo apt install aws-neuron-dkms` or `sudo yum install aws-neuron-dkms`

11.3.2 Application fails to start

Neuron Runtime requires Neuron Driver(aws-neuron-dkms package) to access Neuron devices. If the driver is not installed then Neuron Runtime wont able to access the Neuron devices and will fail with an error message in console and syslog.

If `aws-neuron-dkms` is not installed then the error message will be like the following:

```
2021-Aug-11 18:38:27.0917 13713:13713 ERROR   NRT:nrt_init      Unable to determine␣
↪Neuron Driver version. Please check aws-neuron-dkms package is installed.
```

If `aws-neuron-dkms` is installed but does not support the latest runtime then the error message will be like the following:

```
2021-Aug-11 19:18:21.0661 24616:24616 ERROR   NRT:nrt_init      This runtime requires␣
↪Neuron Driver version 2.0 or greater. Please upgrade aws-neuron-dkms package.
```

When using any supported framework from Neuron SDK version 2.5.0 and Neuron Driver (aws-neuron-dkms) versions 2.4 or older, Neuron Runtime will return the following error message:

```
2022-Dec-01 09:34:12.0559   138:138   ERROR   HAL:aws_hal_tpb_pooling_write_profile     ␣
↪ failed programming the engine
```

Solution

Please follow the installation steps in *Setup Guide* to install `aws-neuronx-dkms`.

11.3.3 Neuron Core is in use

A Neuron Core cant be shared between two applications. If an application started using a Neuron Core all other applications trying to use the NeuronCore would fail during runtime initialization with the following message in the console and in syslog:

```
2021-Aug-27 23:22:12.0323 28078:28078 ERROR   NRT:nrt_allocate_neuron_cores
↪ NeuronCore(s) not available - Requested:nc1-nc1 Available:0
```

Solution

Terminate the the process using NeuronCore and then try launching the application again.

11.3.4 Unsupported NEFF Version

While loading a model(NEFF), Neuron Runtime checks the version compatibility. If the version the NEFF is incompatible with Runtime then it would fail the model load with following error message:

```
NEFF version mismatch supported: 1.1 received: 2.0
```

Solution

Use compatible versions of Neuron Compiler and Runtime. Updating to the latest version of both Neuron Compiler and Neuron Runtime is the simplest solution. If updating one of the two is not an option, please refer to the neuron-runtime-release-notes of the Neuron Runtime to determine NEFF version support.

11.3.5 Insufficient Memory

While loading a model(NEFF), Neuron Runtime reserves both device and host memory for storing weights, ifmap and ofmap of the Model. The memory consumption of each model is different. If Neuron Runtime is unable to allocate memory then the model load would fail with the following message in syslog

```
kernel: [XXXXX] neuron:mc_alloc: device mempool [0:0] total 1073741568 occupied
↪960539030 needed 1272 available 768
```

Solution

As the error is contextual to what's going on with your instance, the exact next step is unclear. Try unloading some of the loaded models which will free up device DRAM space. If this is still a problem, moving to a larger Inf1 instance size with additional NeuronCores may help.

11.3.6 Insufficient number of NeuronCores

The NEFF requires more NeuronCores than available on the instance.

Check for error messages in syslog similar to:

```
NRT:  26638:26638 ERROR  TDRV:db_vtpb_get_mla_and_tpb                Could not find VNC␣
↪id n
NRT:  26638:26638 ERROR  NMGR:dlr_kelf_stage                         Failed to create␣
↪shared io
NRT:  26638:26638 ERROR  NMGR:stage_kelf_models                      Failed to stage␣
↪graph: kelf-a.json to NeuronCore
NRT:  26638:26638 ERROR  NMGR:kmgr_load_nn_post_metrics              Failed to load NN:␣
↪xxxxxxx, err: 2
```

Solution

The NeuronCores may be in use by models you are not actively using. Ensure you've unloaded models you're not using and terminated unused applications. If this is still a problem, moving to a larger Inf1 instance size with additional NeuronCores may help.

11.3.7 Numerical Error

Neuron Devices will detect any NaN generated during execution and report it. If Neuron Runtime sees NaNs are generated then it would fail the execution request with Numerical Error with the following message:

```
nrtd[nnnnn]: ....  Error notifications found on NC .... INFER_ERROR_SUBTYPE_NUMERICAL
```

Solution

This usually an indication of either error in the model or error in the input.

Report issue to Neuron by posting the relevant details on GitHub issues.

11.4 Neuron runtime FAQ

Table of Contents

- *Where can I find information about Neuron Runtime 2.x (`libnrt.so`)*
- *What will happen if I will upgrade Neuron Framework without upgrading latest kernel mode driver?*
- *Do I need to recompile my model to use the Runtime Library?*
- *Do I need to change my application launch command?*
- *How do I restart/start/stop the Neuron Runtime?*
- *How do I know which runtimes are associated with which Neuron Device(s)?*
- *What about RedHat or other versions of Linux and Windows?*
- *How can I take advantage of multiple NeuronCores to run multipleinferences in parallel?*

11.4.1 Where can I find information about Neuron Runtime 2.x (`libnrt.so`)

See *Introducing Neuron Runtime 2.x (libnrt.so)* for detailed information about Neuron Runtime 2.x (`libnrt.so`).

11.4.2 What will happen if I will upgrade Neuron Framework without upgrading latest kernel mode driver?

Application start would fail with the following error message: .. code:: bash

> 2021-Aug-11 19:18:21.0661 24616:24616 ERROR NRT:nrt_init This runtime requires Neuron Driver version 2.0 or greater. Please upgrade aws-neuron-dkms package.

11.4.3 Do I need to recompile my model to use the Runtime Library?

No. Runtime 2.x supports all the models compiled with Neuron Compiler 1.x.

11.4.4 Do I need to change my application launch command?

No.

11.4.5 How do I restart/start/stop the Neuron Runtime?

Since Neuron Runtime is a library, starting/stopping application would result in starting/stopping the Neuron Runtime.

11.4.6 How do I know which runtimes are associated with which Neuron Device(s)?

neuron-ls and *neuron-top* can be used to find out applications using Neuron Devices.

11.4.7 What about RedHat or other versions of Linux and Windows?

We don't officially support it yet.

11.4.8 How can I take advantage of multiple NeuronCores to run multipleinferences in parallel?

Examples of this for TensorFlow and MXNet are found here and here.

11.5 Neuron Runtime Release Notes

Neuron Runtime consists of a kernel mode driver and C/C++ libraries which provides APIs to access Neuron Devices. The runtime itself (libnrt.so) is integrated into the ML frameworks for simplicity of deployment. The Neuron Runtime supports training models and executing inference on the Neuron Cores.

Table of contents

- *Known issues*
- *NEFF Support Table:*
- *Neuron Runtime Library [2.10.18.0]*
- *Neuron Runtime Library [2.10.15.0]*
- *Neuron Runtime Library [2.9.64.0]*
- *Neuron Runtime 2.x (`libnrt.so`) release [2.2.51.0]*
- *Neuron Runtime 2.x (`libnrt.so`) release [2.2.31.0]*
- *Neuron Runtime 2.x (`libnrt.so`) release [2.2.18.0]*
- *Neuron Runtime 2.x (`libnrt.so`) release [2.2.15.0]*

11.5.1 Known issues

Updated : 04/29/2022

- In rare cases of multi-process applications running under heavy stress a model load failure my occur. This may require reloading of the Neuron Driver as a workaround.

11.5.2 NEFF Support Table:

Use this table to determine the version of Runtime that will support the version of NEFF you are using. NEFF version is determined by the version of the Neuron Compiler.

NEFF Version	Runtime Version Range	Notes
0.6	*	All versions of RT support NEFF 0.6
1.0	>= 1.0.6905.0	Starting support for 1.0 NEFFs
2.0	>= 1.6.5.0	Starting support for 2.0 NEFFs

11.5.3 Neuron Runtime Library [2.10.18.0]

Date: 11/07/2022

New in this release

- Minor bug fixes and enhancements.

11.5.4 Neuron Runtime Library [2.10.15.0]

Date: 10/26/2022

New in this release

- Changed default runtime behavior to reset NeuronCores when initializing applications. With this change, the reseting of the Neuron Driver after application crash is no longer necessary. The new reset functionality is controled by setting environment variable: `NEURON_RT_RESET_CORES`, see *Neuron Runtime Configuration* for more information.

Bug fixes

- Fixed a bug where Stochastic Rounding was not being set for collective communication operators
- Fixed an issue with triggering DMA for large tensors
- Increased default execution timeout to 30 seconds
- Fixed IOQ resetting queue to incorrect ring id value
- Updated the Neuron driver for more reliable behavior of driver device reset. Driver no longer busy waits on reset or gets stuck waiting on reset, which caused kernel taints or caused driver unload attempts to fail.
- Fixed a bug the prevented collective communication over tensors larger than 2GB
- Fixed a bug that caused intermittent memory corruption when unloading a model
- Fixed a bug that caused the exhausting of EFA memory registration pool after multiple model reloads.

11.5.5 Neuron Runtime Library [2.9.64.0]

Date: 10/10/2022

This release specifically adds support for training workloads on one or more EC2 TRN1 instances.

Required Neuron Driver Version: 2.5 or newer

New in this release

- Broke out runtime into a separate package called aws-neuronx-runtime-lib.
- Added RUNPATH for discovery of libnrt.so, can be overridden with LD_LIBRARY_PATH.
- Added support for multiple collective compute operations, e.g. All-Reduce, Reduce-Scatter, All-Gather.
- Added Send/Recv operation support
- Added support for using multiple DMA engines with single pseudo embedding update instruction.
- Changed instruction buffer alignment to 32K.
- Reduced memory required during NEFF swapping.
- Enabled notifications for send/recv collectives operations.
- Added trace apis in support of execution profiling.
- Added support for TPB reset (default: off).
- Added version checking for libnccom (aws-neuronx-collectives).
- Added new runtime version API.
- Added 8-channel support for Trn1.
- Improved debug outputs.
- Added support for write combining on BAR4.
- Increased default execution timeout from 2 seconds to 30 seconds.
- Improved handling of zero-sized tensors

11.5.6 Neuron Runtime 2.x (`libnrt.so`) release [2.2.51.0]

Date: 03/25/2022

- Fixed an invalid memory access that could occur when unloading models.
- Reduced severity of logging for numerical errors from ERROR to WARN.
- Improved handling of models with numerous CPU operations to avoid inference failure due to memory exhaustion.

11.5.7 Neuron Runtime 2.x (`libnrt.so`) release [2.2.31.0]

Date: 01/20/2022

New in the release

- Changed error notifications from `WARN` to `ERROR` in cases when the causing problem is non-recoverable.
- Changed handling of inference timeouts (`NERR_TIMEOUT`) to avoid failure when the timeout is related to a software thread scheduling conflict.

Bug fixes

- Increased the number of data queues in Neuron Runtime 2.x to match what was previously used in Neuron Runtime 1.x. The use of fewer number of data queues in Neuron Runtime 2.x was leading to crashes in a limited number of models.
- Fixed the way Neuron Runtime 2.x updates the inference end timestamp. Previously, Neuron Runtime 2.x update of the inference end timestamp would have lead to a negative latency statistics in neuron-monitor with certain models.

11.5.8 Neuron Runtime 2.x (`libnrt.so`) release [2.2.18.0]

Date: 11/05/2021

- Resolved an issue that affect the use of Neuron within container. In previous Neuron Runtime release (libnrt.so.2.2.15.0), when /dev/neuron0 was not used by the application, Neuron Runtime attempted and failed to initialize /dev/neuron0 because user didn't pass /dev/neuron0 to the container. this Neuron Runtime release (`libnrt.so.2.2.18.0`) allows customers to launch containers with specific NeuronDevices other than /dev/neuron0.

11.5.9 Neuron Runtime 2.x (`libnrt.so`) release [2.2.15.0]

Date: 10/27/2021

New in this release

- *First release of Neuron Runtime 2.x* - In this release we are introducing Neuron Runtime 2.x which is a shared library named (`libnrt.so`) and replacing Neuron Runtime 1.x server (`neruon-rtd`) . Upgrading to `libnrt.so` improves throughput and latency, simplifies Neuron installation and upgrade process, introduces new capabilities for allocating NeuronCores to applications, streamlines container creation, and deprecates tools that are no longer needed. The new library-based runtime (`libnrt.so`) is integrated into Neuron's ML Frameworks (with the exception of MXNet 1.5) and Neuron Tools packages directly - users no longer need to install/deploy the `aws-neuron-runtime`package.

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.

- Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

11.6 Neuron Driver Release Notes

Table of contents

- *Known issues*
- *Neuron Driver release [2.6.26.0]*
- *Neuron Driver release [2.5.38.0]*
- *Neuron Driver release [2.3.26.0]*
- *Neuron Driver release [2.3.11.0]*
- *Neuron Driver release [2.3.3.0]*
- *Neuron Driver release [2.2.14.0]*
- *Neuron Driver release [2.2.13.0]*
- *Neuron Driver release [2.2.6.0]*
- *Neuron Driver release [2.1]*

11.6.1 Known issues

Updated : 04/29/2022

- In rare cases of multi-process applications running under heavy stress a model load failure my occur. This may require reloading of the Neuron Driver as a workaround.

11.6.2 Neuron Driver release [2.6.26.0]

Date: 11/07/2022

New in this release

- Minor bug fixes and improvements.

11.6.3 Neuron Driver release [2.5.38.0]

Neuron Driver now supports INF1 and TRN1 EC2 instance types. Name of the driver package changed from aws-neuron-dkms to aws-neuronx-dkms. Please remove the older driver package before installing the newest one.

Date: 10/10/2022

New in this release

- Support added for EC2 Trn1 instance types and ML training workloads.
- Added missing GPL2 LICENSE file.
- Changed package name to aws-neuronx-dkms (was previously minus the 'x').
- Security Update – blocked user space access to control registers and DMA control queues intended to be used by the Neuron Driver only.
- Added support for DMA Aborts to avoid hangs.
- Added support for TPB Reset.
- Added sysfs entries for triggering resets and reading core counts.
- Added write combining on BAR4.
- Added PCI Device ID update as part of install.
- Added handling for known duplicate device id error.

Bug Fixes

- Fixed a null pointer free scenario.
- Fixed installation issue related to install without internet connectivity.

11.6.4 Neuron Driver release [2.3.26.0]

Date: 08/02/2022

Bug Fixes

- Security Update: Blocked user space access to control registers and DMA control queues intended to be used by the Neuron Driver only. Recommending upgrade to all customers.

11.6.5 Neuron Driver release [2.3.11.0]

Date: 05/27/2022

New in this release

- This driver is required to support future releases of the Neuron Runtime. Included in the release is both a bug fix to avoid a kernel crash scenario and an increased compatibility range to ensure compatibility with future versions of Neuron Runtime.

Bug Fixes

- Correction to huge aligned memory allocation/freeing logic that was previously susceptible to crashes in the kernel. The crash would bring down the OS. Recommending upgrade to all customers.

11.6.6 Neuron Driver release [2.3.3.0]

Date: 04/29/2022

New in this release

- Minor performance improvements on inference and loading of models.

Bug Fixes

- Reduced Host CPU usage when reading `hw_counters` metric from neuron-monitor
- Minor bug fixes.

11.6.7 Neuron Driver release [2.2.14.0]

Date: 03/25/2022

New in this release

- Minor updates

11.6.8 Neuron Driver release [2.2.13.0]

Date: 01/20/2022

New in this release

- Minor updates

11.6.9 Neuron Driver release [2.2.6.0]

Date: 10/27/2021

New in this release

- Memory improvements made to ensure all allocations are made with 4K alignments.

Resolved issues

- No longer delays 1s per NeuronDevice when closing Neuron Tools applications.
- Fixes a Ubuntu 20 build issue

11.6.10 Neuron Driver release [2.1]

- Support is added for Neuron Runtime 2.x (`libnrt.so`).
- Support for previous releases of Neuron Runtime 1.x is continued with Driver 2.x releases.

This document is relevant for: `Inf1`, `Trn1`

This document is relevant for: `Trn1`

11.7 Neuron Collectives Release Notes

Neuron Collectives refers to a set of libraries used to support collective compute operations within the Neuron SDK. The collectives support is delivered via the aws-neuronx-collectives package and includes a pre-built version of the OFI plugin required for use of collectives with Elastic Fabric Adapter (EFA).

Table of contents

- *Neuron Collectives [2.10.20.0]*
- *Neuron Collectives [2.9.86.0]*

11.7.1 Neuron Collectives [2.10.20.0]

Date: 10/10/2022

New in this release

- Improved logging to appear similar in style to Neuron Runtime

Bug Fixes

- Fixed memory registration to support 2GB+ sizes
- Fixed association of network devices to channels (removes previous hard-coding).

11.7.2 Neuron Collectives [2.9.86.0]

Date: 10/10/2022

New in this release

- Added support for All-Reduce, Reduce-Scatter, All-Gather, and Send/Recv operations.

This document is relevant for: `Inf1`, `Trn1`

CHAPTER

TWELVE

NEURON COMPILER

The Neuron Compiler accepts Machine Learning models in various formats (TensorFlow, MXNet, PyTorch, XLA HLO) and optimizes them to run on Neuron devices.

The Neuron compiler is invoked within the ML framework, where ML models are sent to the compiler by the Neuron Framework plugin. The resulting compiler artifact is called a NEFF file (Neuron Executable File Format) that in turn is loaded by the Neuron runtime to the Neuron device.

Neuron Compiler for Trn1

API Reference Guide

This document is relevant for: `Trn1`

12.1 Neuron Compiler CLI Reference Guide (`neuronx-cc`)

This document describes the command line interface of the Neuron Compiler.

This reference is not relevant for applications that run the Neuron Compiler from within a machine learning framework (*PyTorch-Neuron* for example) since these options are passed from the framework directly to the compiler. Using the compiler command line may be desirable for applications that do not use a framework or customize existing frameworks. It is also possible to specify compiler options within the framework which will forward these options to the compiler using *NEURON_CC_FLAGS*.

12.1.1 Usage

Optional parameters are shown in square brackets.

Neuron Compiler Command-Line Interface

`neuronx-cc` `<command> [parameters]`

Common parameters for the Neuron CLI:

- `--verbose`: Specify the level of output produced by the compiler. (Default: `warning`)

  Valid values:

  - `info`: Informational messages regarding the progress of model compilation (written to stdout).

  - warning: Diagnostic messages that report model code that is not inherently erroneous but may be risky or suggest there may have been an error (written to stderr).
  - error: The compiler detected a condition causing it not complete the compilation successfully (written to stderr).
  - critical: The compiler encountered an unrecoverable error terminates immediately (written to stderr).
  - debug: Extensive information regarding the compiler's internal execution phases (written to stdout).
- --help: Display a usage message of compiler options.

  Use neuronx-cc <command> --help for information on a specific command.

Available Commands:

- compile
- list-operators

neuronx-cc compile [parameters]

Compile a model for use on the AWS Machine Learning Accelerator.

```
neuronx-cc compile <model_files>
--framework <framework_name>
--target <instance_family>
[--auto-cast <cast_mode>]
[--auto-cast-type <data_type>]
[--model-type <model>]
[--enable-fast-context-switch>]
[--enable-fast-loading-neuron-binaries]
[--logfile <filename>]
[--neuroncore-pipeline-cores <count>]
[--output <filename>]
```

Compile Parameters:

- <model_files>: Input containing model specification.

  The number of arguments required varies between frameworks:

  - **XLA**: A local filename of a HLO file (hlo.pb) generated via XLA. See hlo.proto for the .proto description and inspect-compiled-programs for more information on how to generate such files.
- --framework: Framework used to generate training model.

  Valid values:

  - XLA
- --target: Name of the Neuron instance family on which the compiled model will be run.

  Valid values:

  - trn1
- --model-type: Permit the compiler to attempt model-specific optimizations based upon type of model being compiled. (Default: generic)

  Valid values:

  - generic

  - `transformer` (wikipedia)

- `--auto-cast`: Controls how the compiler makes tradeoffs between performance and accuracy for FP32 operations. (Default: `matmult`)

  Valid values:

  - `matmul`: Only cast FP32 operations that use the Neuron matrix-multiplication engine.
  - `all`: Cast all FP32 operations to achieve highest performance. This option can potentially lower precision/accuracy.
  - `none`: Leave all data types as defined in the model. Do not apply auto-casting data type optimizations.

  A more complete discussion on how to use this option and its arguments is in *Mixed Precision and Performance-accuracy Tuning for Training*.

  Note: If the `--auto-cast` option is specified, the `--auto-cast-type` compiler flag can be optionally set to define which lower-precision data type the compiler should use.

- `--auto-cast-type`: When auto-cast mode is enabled, cast the FP32 operators to the lower-precision data type specified by this option. (Default: `bf16`)

  Valid values:

  - `bf16`: Cast the FP32 operations selected via the `--auto-cast` option to BF16 to achieve highest performance and preserve dynamic range.
  - `fp16`: Cast the FP32 operations selected via the `--auto-cast` option to FP16 to achieve improved performance relative to FP32 and increased precision relative to BF16.
  - `tf32`: Cast the FP32 operations selected via the `--auto-cast` option to TensorFloat-32.

  Note: If multiple competing options are specified then the option later in the command line will supercede previous options.

- `--enable-fast-context-switch`: Optimize for faster model switching rather than execution latency.

  This option will defer loading some weight constants until the start of model execution. This results in overall faster system performance when your application switches between models frequently on the same Neuron Core (or set of cores).

- `--enable-fast-loading-neuron-binaries`: Save the compilation output file in an uncompressed format.

  This creates executable files which are larger in size but faster for the Neuron Runtime to load into memory during model execution.

- `--logfile`: Filename where compiler writes log messages. (Default: "log-neuron-cc.txt").
- `--neuroncore-pipeline-cores`: Number of Neuron Cores to be used in "NeuronCore Pipeline" mode for low-latency inference. (Default: 1)

  Note: This is not used to define the number of Neuron Cores to be used in a data parallel deployment (i.e., the same model on multiple Neuron Cores). That is a Runtime/Framework configuration choice. Refer to *Parallel Execution using NEURON_RT_NUM_CORES* for more details.

- `--output`: Filename where compilation output (NEFF archive) will be recorded. (Default: "file.neff")

Example:

Compiling an XLA HLO:

```
neuronx-cc compile bert-model.hlo --framework XLA --target trn1 --model-
↪type transformer --output bert.neff
```

neuronx-cc `list-operators [parameters]`

Returns a newline ('\n') separated list of operators supported by the Neuron Compiler.

```
neuronx-cc list-operators
--framework <value>
```

List-Operators Parameters:

- `--framework`: Framework in which the operators were registered.

  Valid values:

  - `XLA`: Operator names will be formatted according to the value used by XLA compiler in XlaBuilder.

Example:

```
neuronx-cc list-operators -framework XLA
...
```

Exit Statuses:

- **0**: Compilation succeeded
- **<>0**: An error occurred during compilation.

This document is relevant for: `Trn1`

Developer Guide

This document is relevant for: `Trn1`

12.2 Mixed Precision and Performance-accuracy Tuning (`neuronx-cc`)

Table of contents

- *Overview*
- *Neuron Hardware*
- *Performance-accuracy tradeoffs*
- *What is the difference between Data Types?*
- *Should I downcast operations to smaller Data Types?*

12.2.1 Overview

The Neuron Compiler supports machine learning models with FP32, TF32, FP16 and BF16 (Bfloat16) tensors and operators. The Neuron hardware supports a mix of 32, 16, and 8 bit datatypes. This guide explains how to apply the available auto-cast methods and their performance / accuracy trade-offs when compiling a model with Neuron.

Note: Neuron Compiler support for INT8 is planned for a future Neuron SDK release. See Neuron Compiler: Enable Neuron INT8 support for details.

12.2.2 Neuron Hardware

The Neuron v2 hardware supports matrix multiplication using FP16, BF16, TF32, and FP32 on its matrix multiply ("matmult") engine, and accumulations using FP32. Operators such as activations or vector operations are supported using FP32, TF32, FP16, and BF16. Supporting FP16 and BF16 allows Neuron to have significantly higher performance than executing everything as FP32.

12.2.3 Performance-accuracy tradeoffs

By default, the Neuron Compiler will **automatically cast FP32 matrix multiplication operations to BF16**. The remaining operations are performed in the data type specified by the model. The Neuron Compiler provides CLI options that direct the compiler to cast to other data types, thereby giving the ability to choose an accuracy-to-performance tradeoff in model execution. Deciding what CLI settings to use will be application specific and may require some experimentation. See *Neuron Compiler CLI Reference Guide* for details.

12.2.4 What is the difference between Data Types?

The NeuronCore v2 support multiple data types (see *NeuronCore v2 Data Types*). Each data type provides benefits and drawbacks due to its dynamic range and numeric precision.

Type	Minimum	Maximum	Strength	Weakness
FP16	-65504	65504	Numeric Precision, High granularity, Mid-range numbers	Low range, medium precision
BF16	-3.40E+38	3.40E+38	Dynamic Range, Extremely small/large numbers	Low precision
TF32	-3.40E+38	3.40E+38	Dynamic Range, Extremely small/large numbers	Medium precision
FP32	-3.40E+38	3.40E+38	N/A	Larger model size, potentially slower computation

- FP16 provides a high density of representable values that are neither extremely small or extremely large. The density of representable values within the range is approximately an order of magnitude greater than BF16.
  - Conversion from FP32 to FP16 will perform well when values are relatively small but non-extreme (either very small or very large).
  - Conversion from FP32 to FP16 will perform badly if the original FP32 values are outside of the range of FP16. This will produce inf/-inf values and may result in NaN depending on the operation.
- BF16 provides a wider range of representable values which includes both very small and very large values. However, the overall density of representable values is usually lower than FP16 for more non-extreme values.

The range is nearly identical to the range of FP32 but because the number of bits is halved, this means the individual values are sparse.

- Conversion from FP32 to BF16 will perform well when the values are well-distributed throughout the range. Since BF16 covers the entire FP32 range, this means each original value can map to a relatively close downcast value.
- Conversion from FP32 to BF16 will perform badly when fine granularity is needed. Since BF16 granularity is sacrificed for greater range it will almost always map worse to values that are within the FP16 range.

12.2.5 Should I downcast operations to smaller Data Types?

This choice here is driven entirely by accuracy vs performance tradeoff. Casting operations to smaller 16-bit data types will provide a significant performance benefit but may end up sacrificing accuracy.

The compiler uses BF16 casting **by default** for matrix multiplication operations. The speedup from casting operations gives a significant performance boost and the range of representable values in BF16 allows for more safety compared to FP16 when the possible numeric range of input values is unknown.

The Neuron Compiler's `--auto-cast` and `--auto-cast-type` CLI options are used to direct the compiler to perform alternate casting operations. See the detailed list of the options in *Neuron v2 Compiler CLI Reference Guide*.

It is recommended that you start with compiling the model to achieve high performance (default), you can then test the accuracy of the application and, if needed, try the next higher precision casting option until the desired accuracy and performance are achieved.

The option combinations to consider in a typical flow are:

Note that compiler has to preserve the input/output (i/o) tensor types requested by Framework, therefore no casting is done on the i/o tensors. Additional speedup can be obtained by casting them in the Framework prior to compilation.

To learn how to configure the compiler options from within your application's framework, please see:

This document is relevant for: `Trn1`

This document is relevant for: `Trn1`

12.3 Neuron Compiler FAQ (`neuronx-cc`)

Table of contents

- *Where can I compile to Neuron?*
- *What is the difference between* `neuron-cc` *and* `neuronx-cc`*?*
- *Should I use* `neuron-cc` *or* `neuronx-cc`*?*
- *My current neural network is based on FP32, how can I use it with Neuron?*
- *Which operators does Neuron support?*
- *Any operators that Neuron Compiler doesn't support?*
- *Will I need to recompile again if I updated runtime/driver version?*
- *I have a NEFF binary, how can I tell which compiler version generated it?*

- *How long does it take to compile?*
- *Why is my model producing different results compared to CPU/GPU?*
- *Do you support model* <insert model type>*?*

12.3.1 Where can I compile to Neuron?

The one-time compilation step from the standard framework-level model to NEFF binary may be performed on any EC2 instance or even on-premises.

We recommend using a high-performance compute server of choice (C5 or z1d instance types), for the fastest compile times and ease of use with a prebuilt DLAMI. Developers can also install Neuron in their own environments; this approach may work well for example when building a large fleet for inference, allowing the model creation, training and compilation to be done in the training fleet, with the NEFF files being distributed by a configuration management application to the inference fleet.

12.3.2 What is the difference between `neuron-cc` and `neuronx-cc`?

- `neuron-cc` is the Neuron Compiler with TVM front-end, ``neuron-cc``supports only *NeuronCore-v1 Architecture*.
- `neuronx-cc` is the Neuron Compiler with XLA fron-end, `neuronx-cc` currently supports *NeuronCore-v2 Architecture*, `neuronx-cc` support of *NeuronCore-v1 Architecture* is currently a *Roadmap Item*.

12.3.3 Should I use `neuron-cc` or `neuronx-cc`?

See *What is the difference between neuron-cc and neuronx-cc?*

12.3.4 My current neural network is based on FP32, how can I use it with Neuron?

Developers who want to train their models in FP32 for best accuracy can compile and deploy them with Neuron. The Neuron compiler automatically converts FP32 to internally supported datatypes, such as FP16 or BF16. You can find more details about FP32 data type support and performance and accuracy tuning in *Mixed Precision and Performance-accuracy Tuning (neuronx-cc)* or *Mixed precision and performance-accuracy tuning (neuron-cc)*. The Neuron compiler preserves the application interface - FP32 inputs and outputs. Transferring such large tensors may become a bottleneck for your application. Therefore, you can improve execution time by casting the inputs and outputs to FP16 or BF16 in the ML framework prior to compilation.

12.3.5 Which operators does Neuron support?

You can use the `neuronx-cc list-operators` command on the cli to list the operators. See *Neuron Compiler CLI Reference Guide (neuronx-cc)*.

To request support for new operators, open an issue on our GitHub forum.

12.3.6 Any operators that Neuron Compiler doesn't support?

Models with control-flow and dynamic shapes are not supported now. You will need to partition the model using the framework prior to compilation.

Note: Starting with *NeuronCore-v2 Architecture* Neuron supports control-flow and dynamic shapes.

Stay tuned and follow the *Neuron Roadmap*.

12.3.7 Will I need to recompile again if I updated runtime/driver version?

The compiler and runtime are committed to maintaining compatibility for major version releases with each other. The versioning is defined as major.minor, with compatibility for all versions with the same major number. If the versions mismatch, an error notification is logged and the load will fail. This will then require the model to be recompiled.

12.3.8 I have a NEFF binary, how can I tell which compiler version generated it?

** We will bring a utility out to help with this soon.

12.3.9 How long does it take to compile?

It depends on the model and its size and complexity, but this generally takes a few minutes.

12.3.10 Why is my model producing different results compared to CPU/GPU?

NeuronCore-v2 Architecture supports multiple casting modes for floating point numbers, each with associated implications for performance and accuracy. The default casting mode is a pragmatic balance between performance and accuracy, however on some models it may result in loss of precision.

See the `--auto-cast` and `--auto-cast-type` options in *Neuron Compiler CLI Reference Guide (neuronx-cc)* for details on how to adjust the casting mode.

12.3.11 Do you support model <*insert model type*>?

`neuronx-cc` has explicit support for select model families using the `--model-type` option, though many other model types are supported. You can also inspect supported operators using the `list-operators` sub-command. See th *Neuron Compiler CLI Reference Guide (neuronx-cc)* for details. More generally, support for new operators and models is continually being added. See our *Roadmap* for details.

This document is relevant for: `Trn1`

This document is relevant for: `Trn1`

12.4 Neuron Compiler (neuronx-cc) release notes

Table of Contents

- *Neuron Compiler [2.3.0.4]*
- *Neuron Compiler [2.2.0.73]*
- *Neuron Compiler [2.1.0.76]*
  - *Known issues*
- *Supported Operators*

12.4.1 Neuron Compiler [2.3.0.4]

Date: 12/09/2022

- Added support for the following HLO operators: `rev (reverse)`.
- The `pow()` function can now handle both integer and floating-point exponents.
- Optimization enhancements and bug fixes to improve model execution performance.

12.4.2 Neuron Compiler [2.2.0.73]

Date: 10/27/2022

- Adding support for the following HLO operators: `LogicalNot`, `atan2` and `DynamicUpdateSlice` (for constant index).

12.4.3 Neuron Compiler [2.1.0.76]

Date: 10/5/2022

The Neuron Compiler is an Ahead-of-Time compiler that accelerates models for execution on NeuronCores. This release supports compiling models for training on a Trn1 instance using Pytorch Neuron. Users typically access the compiler via the Framework to perform model compilation, although it can also be run as a command line tool (*neuronx-cc*).

The Neuron Compiler supports compiling models for mixed precision calculations. The trn1 hardware supports matrix multiplication using FP16, BF16, and FP32 on its Matrix Multiplication Engine, and accumulations using FP32. Operators such as activations or vector operations are supported using FP16, BF16, and FP32. Tensor transpose can be accomplished in FP16, BF16, FP32, or TF32 datatypes. By default, scalar and vector operations on FP32 values will be done in FP32, while matrix multiplications are cast to BF16 and transpose operations are cast to FP32. This default casting will generate the highest performance for a FP32 trained model.

By default, the compiler will target maximum performance by automatically casting the model to mixed precision. It also provides an option (`--auto-cast`) that allows the user to make tradeoffs between higher performance and optimal accuracy. The decision on what option argument to use with the `--auto-cast` option will be application specific. Compiler CLI options can be passed to the compiler via the framework.

Known issues

- The Random Number Generator operation can be passed an initial seed value, however setting the seed is not supported in this release.
- The exponent value of the pow() function must be a compile-time integer constant.
- The compiler treats INT64 datatypes as INT32 by truncating the high-order bits. If possible, cast these values to 32 bits .
- Model compilation time is proportional to the model size and operators used. For some larger NLP models it may be upwards of 30 minutes.

12.4.4 Supported Operators

The following XLA operators are supported by the Neuron Compiler. Future releases will broaden model support by providing additional XLA operators defined in https://www.tensorflow.org/xla/operation_semantics.

The list of supported operators can also be retrieved from the command line using *neuronx-cc list-operators*.

Supported XLA Operators	Notes
Abs	
Add	
Allgather	
Allreduce

Neuron Compiler for Inf1

API Reference Guide

This document is relevant for: `Inf1`

12.5 Neuron compiler CLI Reference Guide (`neuron-cc`)

This document describes the command line interface of the Neuron compiler. This reference is not relevant for applications that run neuron-cc from within a machine learning framework (TensorFlow-Neuron for example) since these options are passed from the framework directly to neuron-cc.

Using neuron-cc on the command line may be desirable for applications that do not use a framework, or customize existing frameworks. It is also possible to supply CLI commands to the framework as options to be passed through to the compiler.

12.5.1 Usage

Optional parameters are shown in square brackets. See the individual framework guides for the correct syntax.

Neuron Compiler CLI

neuron-cc `[options] <command> [parameters]`

Common options for the Neuron CLI:

- `--verbose` (string) default="WARN":

  Valid values:

  - `DEBUG`
  - `INFO`
  - `WARN`
  - `ERROR`

Use `neuron-cc <command> --help` for information on a specific command.

Available Commands:

- `compile`
- `list-operators`

neuron-cc `compile [parameters]`

Compile a model for use on the AWS Inferentia Machine Learning Accelerator.

```
neuron-cc compile <file names> --framework <value> --io-config <value> [--
↪neuroncore-pipeline-cores <value>] [--enable-fast-loading-neuron-binaries] [--
↪enable-fast-context-switch] [--fp32-cast cast-method] [--fast-math cast-method] [-
↪-output <value>]
```

Compile Parameters:

- `<file names>`: Input containing model specification. The number of arguments required varies between frameworks:

  - **TENSORFLOW**: A local filename or URI of a TensorFlow Frozen GraphDef (.pb); or the name of a local directory containing a TensorFlow SavedModel.

    See https://github.com/tensorflow/tensorflow/blob/master/tensorflow/core/framework/graph.proto for the associated .proto schema for TensorFlow Frozen GraphDefs. See https://www.tensorflow.org/guide/saved_model for more information on the SavedModel format.

  - **MXNET**: List of local filenames or URIs where input architecture .json file and parameter .param file are stored. These contains information related to the architecture of your graph and associated parameters, respectively.

- `--framework` (string): Framework in which the model was trained.

  Valid values:

  - `TENSORFLOW`
  - `MXNET`

  - XLA

- `--neuroncore-pipeline-cores` (int) (default=1): Number of neuron cores to be used in "NeuronCore Pipeline" mode. This is different from data parallel deployment (same model on multiple neuron cores). Refer to Runtime/Framework documentation for data parallel deployment options.

  Compile for the given number of neuron cores so as to leverage NeuronCore Pipeline mode.

  Note: This is not used to define the number of Neuron Cores to be used in a data parallel deployment (ie the same model on multiple Neuron Cores). That is a runtime/framework configuration choice.

- `--output` (string) (default="out.neff"): Filename where compilation output (NEFF archive) will be recorded.

- `--io-config` (string): Configuration containing the names and shapes of input and output tensors.

  The io-config can be specified as a local filename, a URI, or a string containing the io-config itself.

  The io-config must be formatted as a JSON object with two members "inputs" and "outputs". "inputs" is an object mapping input tensor names to an array of shape and data type. "outputs" is an array of output tensor names. Consider the following example:

```
{
 "inputs": {
    "input0:0": [[1,100,100,3], "float16"],
    "input1:0": [[1,100,100,3], "float16"]
 },
 "outputs": ["output:0"]
}
```

- `--enable-fast-loading-neuron-binaries` : Write the compilation output (NEFF archive) in uncompressed format which results in faster loading of the archive during inference.

- `--enable-fast-context-switch` : Optimize for faster model switching rather than inference latency. This results in overall faster system performance when your application switches between models frequently on the same neuron core (or set of cores). The optimization triggered by this option for example defers loading some weight constants until the start of inference.

- `--fast-math` : Controls tradeoff between performance and accuracy for fp32 operators. See more suggestions on how to use this option with the below arguments in *Mixed precision and performance-accuracy tuning (neuron-cc)*.

  - `all` (Default): enables all optimizations that improve performance. This option can potentially lower precision/accuracy.

  - `none` : Disables all optimizations that improve performance. This option will provide best precision/accuracy.

  - Tensor transpose options

    * `fast-relayout`: Only enables fast relayout optimization to improve performance by using the matrix multiplier for tensor transpose. The data type used for the transpose is either FP16 or BF16, which is controlled by the `fp32-cast-xxx` keyword.

    * `no-fast-relayout`: Disables fast relayout optimization which ensures that tensor transpose is bit-accurate (lossless) but slightly slower.

  - Casting options

  * `fp32-cast-all` (Default): Cast all FP32 operators to BF16 to achieve highest performance and preserve dynamic range. Same as setting `--fp32-cast all`.
  * `fp32-cast-all-fp16`: Cast all FP32 operators to FP16 to achieve speed up and increase precision versus BF16. Same setting as `--fp32-cast all-fp16`.
  * `fp32-cast-matmult`: Only cast FP32 operators that use Neuron Matmult engine to BF16 while using FP16 for matmult-based transpose to get better accuracy. Same as setting `--fp32-cast matmult`.
  * `fp32-cast-matmult-bf16`: Cast only FP32 operators that use Neuron Matmult engine (including matmult-based transpose) to BF16 to preserve dynamic range. Same as setting `--fp32-cast matmult-bf16`.
  * `fp32-cast-matmult-fp16`: Cast only FP32 operators that use Neuron Matmult engine (including matmult-based transpose) to fp16 to better preserve precision. Same as setting `--fp32-cast matmult-fp16`.

Important:

- `all` and `none` are mutually exclusive
- `all` is equivalent to using `fp32-cast-all fast-relayout` (best performance)
- `none` is equivalent to using `fp32-cast-matmult-bf16 no-fast-relayout` (best accuracy)
- `fp32-cast-*` options are mutually exclusive
- `fast-relayout` and `no-fast-relayout` are mutually exclusive
- The `fp32-cast-*` and `*-fast-relayout` options will overwrite the default behavior in `all` and `none`.
- For backward compatibility, the `--fp32-cast` option has higher priority over `--fast-math`. It will overwrite the FP32 casting options in any of the `--fast-math` options if `--fp32-cast` option is present explicitly.

- `--fp32-cast` : Refine the automatic casting of fp32 tensors. This is being replaced by a newer –fast-math.

Important:

- `--fp32-cast` option is being deprecated and `--fast-math` will replace it in future releases.
- `--fast-math` is introducing the `no-fast-relayout` option to enable lossless transpose operation.

The `--fp32-cast` is an interface for controlling the performance and accuracy tradeoffs. Many of the `--fast-math` values invoke (override) it.

- `all` (default): Cast all FP32 operators to BF16 to achieve speed up and preserve dynamic range.
- `matmult`: Cast only FP32 operators that use Neuron Matmult engine to BF16 while using fp16 for matmult-based transpose to get better accuracy.
- `matmult-fp16`: Cast only FP32 operators that use Neuron Matmult engine (including matmult-based transpose) to fp16 to better preserve precision.

- `matmult-bf16`: Cast only FP32 operators that use Neuron Matmult engine (including matmult-based transpose) to BF16 to preserve dynamic range.
- `all-fp16`: Cast all FP32 operators to FP16 to achieve speed up and better preserve precision.

Log Levels:

Logs at levels "trace", "debug", and "info" will be written to STDOUT.

Logs at levels "warn", "error", and "fatal" will be written to STDERR.

Exit Status

0 - Compilation succeeded

>0 - An error occurred during compilation.

Examples

Compiling a saved TensorFlow model:

```
neuron-cc compile test_graph_tfmatmul.pb --framework TENSORFLOW --io-config␣
↪test_graph_tfmatmul.config
```

Compiling a MXNet model:

```
neuron-cc compile lenet-symbol.json lenet-0001.params --framework MXNET --
↪neuroncore-pipeline-cores 2 --output file.neff
```

Compiling an XLA HLO:

```
neuron-cc compile bert-model.hlo --framework XLA  --output file.neff
```

neuron-cc `list-operators [parameters]`

Returns a newline ('n') separated list of operators supported by the NeuronCore.

- **TENSORFLOW**: Operators will be formatted according to the value passed to the associated REGISTER_OP("OperatorName") macro.

  See https://www.tensorflow.org/guide/create_op#define_the_op_interface for more information regarding operator registration in TensorFlow.

- **MXNET**: Operator names will be formatted according to the value passed to the associated NNVM_REGISTER_OP(operator_name) macro.
- **XLA**: Operator names will be formatted according to the value used by XLA compiler in XlaBuilder.

  See https://www.tensorflow.org/xla/operation_semantics for more information regarding XLA operator semantics in XLA interface.

```
neuron-cc list-operators --framework <value>
```

- `--framework` (string): Framework in which the operators were registered.

  Valid values:

  - `TENSORFLOW`
  - `MXNET`
  - `XLA`

Exit Status

0 - Call succeeded

>0 - An error occurred

Example

```
$ neuron-cc list-operators --framework TENSORFLOW
AddN
AdjustContrastv2
CheckNumbers
...
```

Developer Guide

This document is relevant for: `Inf1`

12.6 Mixed precision and performance-accuracy tuning (`neuron-cc`)

Table of contents

- *Neuron Hardware*
- *Performance-accuracy tradeoffs for models trained in FP32*
- *Compiler casting options*
  - *`--fast-math` option*

The Neuron Compiler supports machine learning models with FP32, FP16 and BF16 (Bfloat16) tensors and operators. The Neuron hardware supports a mix of 32 and 16 bit datatypes. The available auto-cast methods and their performance / accuracy trade-offs are explained in this document.

12.6.1 Neuron Hardware

The Neuron hardware supports matrix multiplication using FP16 or BF16 on its Matmult Engine, and accumulations using FP32. Similarly, operators such as activations or vector operations are supported using FP16, BF16 and FP32. Neuron supports tensor transpose in two ways - by fast matrix multiplication in FP16/BF16 or by slower byte-by-byte data movements.

12.6.2 Performance-accuracy tradeoffs for models trained in FP32

Models that are trained using FP32 data types can be deployed on Neuron through ahead of time compilation using the *Neuron Compiler*.

By default, the Neuron Compiler will **cast all FP32 tensors, weights and operations to BF16**. Only partial sums are left in FP32. The default, casting will generate the highest performance for a FP32 trained model.

Using the `--fast-math` CLI option, you can choose the right tradeoff between performance and accuracy. The tradeoff usually is between achieving high performance or optimal accuracy, and decision what settings to use will be application specific.

It is recommended that the you start with compiling the model to achieve the high performance (default), you can then test the accuracy of the application and, if needed, try the next higher precision casting option until the desired accuracy and performance are achieved. A typical flow can be:

1. You can compile without options (default) or with `--fast-math all` which will optimize for performance.
2. If accuracy is not sufficient you can try `--fast-math fp32-cast-matmult`
3. If accuracy is not sufficient you can try `--fast-math fp32-cast-matmult no-fast-relayout`
4. If accuracy is not sufficient you can try `--fast-math none` which will optimize for accuracy .

Between step 2 and step 3, and between step 3 and step 4 you have additional options that can provide different level of accuracy and which are explained in the below section.

Note that compiler has to preserve the input/output (i/o) tensor types requested by Framework, therefore no casting is done on the i/o tensors. Additional speedup can be obtained by casting them in the Framework prior compilation.

To learn how to use compiler command line interface (CLI) options with your application's framework, please see *PyTorch-Neuron trace python API*, *TensorFlow 1.x (tensorflow-neuron) Compilation API* and *TensorFlow 2.x (tensorflow-neuron) Tracing API*.

12.6.3 Compiler casting options

`--fast-math` option

The `--fast-math` option is intended to replace the `--fp32-cast` option. It is recommended to to start using or migrating to `--fast-math` option. The `--fast-math` option provides the same level of functionality as the `--fp32-cast` option in addition to the following:

- The `--fast-math` option introduces the `no-fast-relayout` option to enable lossless transpose operation. This was not possible with the `--fp32-cast` option.
- The `--fast-math` option provides finer control than the `--fp32-cast` option. The transpose operation and the cast operation are controlled independently:
  - `no-fast-relayout` and `fast-relayout` provide control for the transpose operation.
  - `fp32-cast-*` provide control for casting.

See the detailed list of the options in *Neuron compiler CLI Reference Guide (neuron-cc)*.

12.7 Neuron Compiler FAQ (neuron-cc)

Table of contents

- *Where can I compile to Neuron?*
- *My current Neural Network is based on FP32, how can I use it with Neuron?*
- *What are some of the important compiler defaults I should be aware of?*
- *Which operators does Neuron support?*
- *Any operators that Neuron doesn't support?*
- *Will I need to recompile again if I updated runtime/driver version?*
- *I have a NEFF binary, how can I tell which compiler version*
- *How long does it take to compile?*

12.7.1 Where can I compile to Neuron?

The one-time compilation step from the standard framework-level model to NEFF binary may be performed on any EC2 instance or even on-premises.

We recommend using a high-performance compute server of choice (C5 or z1d instance types), for the fastest compile times and ease of use with a prebuilt DLAMI. Developers can also install Neuron in their own environments; this approach may work well for example when building a large fleet for inference, allowing the model creation, training and compilation to be done in the training fleet, with the NEFF files being distributed by a configuration management application to the inference fleet.

12.7.2 My current Neural Network is based on FP32, how can I use it with Neuron?

Developers who want to train their models in FP32 for best accuracy can compile and deploy them with Neuron. The Neuron compiler automatically converts FP32 to internally supported datatypes, such as FP16 or BF16. You can find more details about FP32 data type support and performance and accuracy tuning in *Mixed precision and performance-accuracy tuning (neuron-cc)*. The Neuron compiler preserves the application interface - FP32 inputs and outputs. Transferring such large tensors may become a bottleneck for your application. Therefore, you can improve execution time by casting the inputs and outputs to FP16 or BF16 in the ML framework prior to compilation for Inferentia.

12.7.3 What are some of the important compiler defaults I should be aware of?

The compiler compiles the input graph for a single NeuronCore by default. Using the `--neuroncore-pipeline-cores` option directs the compiler to partition so as to run on a specified number of NeuronCores. This number can be less than the total available NeuronCores on an instance. See *Inferentia Architecture* for more information on NeuronCores.

12.7.4 Which operators does Neuron support?

see *Neuron Supported operators*.

You can also use the "neuron-cc list-operators" command on the cli to list the operators. See neuron-cc-list-operators

If your model contains operators missing from the above list, and you can't reach your performance goals, please post a message on the Neuron developer forum or open a github issue to let us know.

12.7.5 Any operators that Neuron doesn't support?

Models with control-flow and dynamic shapes are not supported. You will need to partition the model using the framework prior to compilation. See the neuron-cc.

12.7.6 Will I need to recompile again if I updated runtime/driver version?

The compiler and runtime are committed to maintaining compatibility for major version releases with each other. The versioning is defined as major.minor, with compatibility for all versions with the same major number. If the versions mismatch, an error notification is logged and the load will fail. This will then require the model to be recompiled.

12.7.7 I have a NEFF binary, how can I tell which compiler version

generated it?** We will bring a utility out to help with this soon.

12.7.8 How long does it take to compile?

It depends on the model and its size and complexity, but this generally takes a few minutes.

12.8.1 Introduction

This document lists the release notes for AWS Neuron compiler. The Neuron Compiler is an ahead-of-time compiler that ensures Neuron will optimally utilize the Inferentia chips.

Operator-support for each input format is provided directly from the compiler.

```
neuron-cc list-operators --framework {TENSORFLOW | MXNET | XLA}
```

The supported operators are also listed here:

Tensorflow: *TensorFlow Neuron (tensorflow-neuron (TF1.x)) Supported operators*

Pytorch: *PyTorch Neuron (torch-neuron) Supported operators*

XLA: neuron-cc-ops-xla

Apache MXNet (Incubating): *Neuron Apache MXNet (Incubating) Supported operators*

12.8.2 Known issues and limitations - updated 11/23/2022

- There is a known issue of increased latency and lower throughput when MLM head is compiled along with BERT model. The workaround is to compile them separately and feed the raw Bert into the head.
- *TensorFlow 2.x* - In this release supported operators are limited to BERT-like models, specifically no conv2d or reduce-window operators are available.
- *Control flow* Neuron only supports control flow operators which are static at compile time. For example static length RNN, top-k, sort.
- *Data layout* The Neuron compiler supports multiple data layout format (NCHW, NHWC, ...). Non-CNHW input/output data-layouts will require Neuron to insert additional transpose operations, causing a degradation in performance.
- *Primary inputs in NeuronCore Pipeline mode* When a neural network is executed in NeuronCore Pipeline mode, only the first operator in a neural network can receive primary inputs from the host.
- *Reduce data type* INT8 data type is not currently supported by the Neuron compiler.
- *NeuronCore Pipeline:* NeuronCorePipeline mode provides low-latency and high-throughput for small batch sizes. We recommend to start testing with batch=1 and gradually increase batch size to fine tune your model throughput and latency performance.
- *Large input tensors* support varies by model. On some models the large input tensors (eg 1024x1024) may result in lower performance or exceeding hardware or compile-time limits, especially on models where the large input tensor is used by many downstream operators. Workarounds may include use of smaller batch, see *Neuron Batching*
- *Conv2d operator* is mapped to Inferentia except for specific cases of extremely large tensors and specific parameters.
- *Conv3d operator* performance is limited when the operator has small number of input channels (< 64).
- FP64 and INT64 input and output tensors are not supported. Please cast to FP32/INT32 in the machine learning framework, prior compiling for Neuron.

12.8.3 Neuron Compiler release [1.13.3.0]

Date: 11/23/2022

- Resolved long compile-times when compiling the YOLOv5 and YOLOv6 models. [GitHub · aws-neuron-sdk · #434]
- Improved the layout algorithm to resolve an issue compiling a transformer-based text recognition model. [GitHub · aws-neuron-sdk · #410]
- Support was added for additional XLA operators

12.8.4 Neuron Compiler release [1.11.7.0]

Date: 08/02/2022

- Fixed a bug for correct handling of mxnet dropout instruction when mode is set as 'training' while performing inference.

12.8.5 Neuron Compiler release [1.11.4.0]

Date: 04/29/2022

- Solved an issue that caused a "false positive" reporting of a data race that may occur due to address overlap.
- Minor bug fixes.

12.8.6 Neuron Compiler release [1.10.3.0]

Date: 03/25/2022

- Minor bug fixes.

12.8.7 Neuron Compiler release [1.9.1.0]

Date: 01/20/2022

- Fixed an issue with frontend compiler for fused operators that was reported in github #362.

12.8.8 Neuron Compiler release [1.8.5.0]

Date: 01/05/2022

New in this release

- Minor bug fixes.

12.8.9 Neuron Compiler release [1.8.2.0]

Date: 12/15/2021

New in this release

- Performance enhancements as a result of improved layout and DMA optimizations.
- Minor bug fixes.

12.8.10 Neuron Compiler release [1.7.3.0]

Date: 10/27/2021

New in this release

- The compiler's list-operators command can now display the supported TensorFlow 2.x operators.
- Support added for new operators in TensorFlow 1.x - ArgMax and ArgMin.
- Introducing the `--fast-math` option for better fine-tuning of accuracy/performance. See *Mixed precision and performance-accuracy tuning (neuron-cc)*

12.8.11 [1.6.13.0]

Date 08/12/2021

New in this release

- TensorFlow 2.x - First support of TensorFlow 2.x. The support is limited to operators in BERT-like models and was tested with Huggingface BERT small, base, large and DistillBert.

Resolved issues

- Fixed compiler backend issue in Tensor_tensor argument distance, github #269

12.8.12 [1.5.5.0]

Date 07/02/2021

Summary

- Robustness and performance improvements.

New in this release

- Added –enable-fast-context-switch to optimize for faster model switching rather than inference latency.
- Deprecated support for ONNX
- Improved robustness of Conv3d
- Corrected compilation error "too many instructions" in DLRM model

12.8.13 [1.4.0.0]

Date 5/28/2021

Summary

- Performance improvements, and usability improvements.

New in this release

- Added uncompressed NEFF format for faster loading models prior inference. Enable it by –enable-fast-loading-neuron-binaries. Some cases of large models may be detrminentally impacted as it will not be compressed but many cases will benefit.
- Corrected compilation error in specific arguments of ResizeBilinear operator

12.8.14 [1.3.0.0]

Date 4/30/2021

Summary

- Performance improvements, new operators, and usability improvements.

New in this release

- Improved performance of batched CNN models like resnet50 with the default compiler options by 10%.
- Improved performance of bert base sequence 128 batch 6 by upto 16%
- Added support for group and depth wise convolution (with limited performance when the number of input channels is small).
- Added more detailed debug names to support for tensorboard.

Resolved Issues

- Corrected potential race condition in overwriting tiles of output tensors.
- Fixed various issues in pipelined inference by enabling fine grain partitioning by default.

12.8.15 [1.2.7.0]

Date 2/24/2021

Summary

Fix for CVE-2021-3177.

12.8.16 [1.2.2.0]

Date 1/30/2021

Summary

Added suport for multiple new operators (see operators list) for Tensoflow and MXNET. Improved inference performance of language, object recognition models on single as well as multiple pipelined cores using neuroncore-pipeline.

New in this release

- The following models are now supported: Resnext 224x224, specific BERT variations applied to natural language processing and translation.
- A number of new operators is now supported on Inferentia, see the full lists *TensorFlow Neuron (tensorflow-neuron (TF1.x)) Supported operators*

  and *Neuron Apache MXNet (Incubating) Supported operators*
- Improved inference performance on yolov4 BERT base sequence 64 (on 16 pipelined cores) and openpose 184.

Resolved Issues

- Corrected a random failure to compile Resnet50 batch 5
- Corrected numerical inaccuracy in RSQRT and related operators for tensors with very large values (> 1e20)

12.8.17 [1.1.7.0]

Date 12/23/2020

Summary

Added suport for PyTorch Yolo V4, a new Framework-visible progress bar and improved inference performance. We continue to streamline the compiler usability by removing the need for options passed to control behavior. We are aiming to remove the need for such options entirely. Some tutorials have been updated to reflect this, but Resnet50 remains in need of these options to achieve maximum performance. Other useability improvements have been added, such as the compiler progress bar. As always, please let us know if there are other areas that we can improve.

New in this release

- Pytorch Yolo V4 is now supported.
- Added a compiler progress bar when compilation is invoked from the Framework. This allows the user to see that progress continues as compilation proceeds, which is useful when compilation takes several minutes. A dot is printed every 20 seconds.
- Improved inference performance of Tensorflow BERT base seq 256 batch 3 by 10% .

Resolved Issues

- Resolved issue with depthwise convolution that manifests as a type check error

12.8.18 [1.0.24045.0]

Date 11/17/2020

Summary

Improved performance for pipelined execution (NeuronCore Pipeline).

New in this release

- NeuronCore Pipeline: improved partitioning to enable better static weights loading to cache.

Resolved Issues

- –static-weights : No longer needed. As this is shown in some examples, please remove the option since the compiler now performs this auto-detection by default.
- –num-neuroncores renamed to –neuroncore-pipeline-cores. The prior option form is still functional (backwards compatible) and will be removed in future releases.
- –batching_en: Resolved compilation failure of ResNet50 FP32 batch 1 on Ubuntu16 when "–batching_en" was used.

12.8.19 [1.0.20600.0]

Date 9/22/2020

Summary

Various performance improvements - both compilation time and inference speed of object recognition models.

- Compiler optimization '-O2' option is now enabled by default.

New in this release

- Improved inference performance of YOLO v3, YOLO v4, VGG16, SSD300. BERT models were improved by an additional 10%.
- Modifed such that -O2 is now the default behavior and does not need to be specified. Note: some tutorials still explicitly specify "-O2". These will be modified in forthcoming updates.

Resolved Issues

- Sped up compilation of large models that were taking hours to sub-40 minute.

12.8.20 [1.0.18001.0]

Date 8/08/2020

Summary

Various performance improvements.

New in this release

Improved performance of BERT base with -O2

Resolved Issues

- n/a

12.8.21 [1.0.17937.0]

Date 8/05/2020

Summary

Various improvements.

12.8.22 [1.0.16861.0]

Date 7/16/2020

Summary

This release has some bug fixes and some functional and performance improvements to support compilation of several neural networks.

New in this release

This release

- Supports compilation of PoseNet, tested for images of specific resolutions upto 736.
- Update the -O2 with a new memory allocator to reduce spilling to DRAM
- Improved performance of the '-O2' on BERT base, and openpose pose network.

Resolved Issues

- Resolved compilation error in Vgg16 batch 1

Other Notes

- Some versions of Inception network may fail to compile in Tensorflow on Ubuntu 16 in conda environment. The symptom is neuron-cc backend data race error. As a workaround use Ubuntu 18, Amazon Linux 2, or virtual env, or use neuron-cc with flag -O2.

Warning: Starting with Neuron 1.14.0, Ubuntu 16 is no longer supported

12.8.23 [1.0.15275.0]

Date 6/11/2020

Summary

This release has some bug fixes and some functional and performance improvements to support compilation of several neural networks.

New in this release

This release

- Supports compilation of PoseNet for images of specific resolutions upto 400x400.
- Improves performance of resnet152.
- Supports a new command line option '-O2' that can help with handling of large tensor inputs for certain models.
- increase NEFF versions to 1.0. This means new NEFFs compiled from this release forward are not compatible with older versions of Neuron Runtime prior to May, 2020 (1.0.6905.0) release. Please update the Neuron Runtime when using NEFF version 1.0.

Resolved Issues

- Compilation issues on prosotron encoder, decoder neural networks.

Other Notes

Dependencies

- This version creates NEFF 1.0 thus may require update of neuron-rtd if older than May 2020 release.

dmlc_nnvm==1.0.2574.0 dmlc_topi==1.0.2574.0 dmlc_tvm==1.0.2574.0 inferentia_hwm==1.0.1362.0 islpy==2018.2

12.8.24 [1.0.12696.0]

Date 5/11/2020

Summary

Bug fixes and some functional and performance improvements to several neural networks.

New in this release

- This version supports compilation of unmodified Tensorflow BERT with batch size 1, 4, 6 for input sequence 128.
- Improved Tensorflow BERT batch 4 sequence 128 performance to 45% of the accelerator peak (from 34%).
- Support for MXNET BERT base batch 8 compilation
- Support for TF Resnet152 batch 2 compilation
- Most compiler messages are migrated from cout to logging mechanisms with verbosity control

Resolved Issues

- Fixed failure to compile unmodified Tensorflow BERT model for small batches
- Fixed run-to-run-variability in OneHot operator implementation
- Robustness improvements for ParallelWavenet and transformer decoder networks

Other Notes

Dependencies

```
dmlc_nnvm==1.0.2356.0
dmlc_topi==1.0.2356.0
dmlc_tvm==1.0.2356.0
inferentia_hwm==1.0.1294.0
islpy==2018.2
```

12.8.25 [1.0.9410.0]

Date 3/26/2020

Summary

Bug fixes and some functional and performance improvements to several neural networks.

New in this release

- Support compilation of modified SSD-300 (*Running SSD300 with AWS Neuron*)
- Improved inference performance in natural language processing networks (such as prosotron encoder) by 45%

Resolved Issues

- Eliminated redundant fp32 to bfloat16 cast on input and output tensors

Known issues and limitations

- See previous releases.

Other Notes

- Added support for faster iteration on recurrent networks (aka auto-loop)

Dependencies

```
dmlc_nnvm==1.0.2049.0
dmlc_topi==1.0.2049.0
pip install --upgrade dmlc_tvm==1.0.2049.0
inferentia_hwm==1.0.897.0
islpy==2018.2
```

12.8.26 [1.0.7878.0]

Date 2/27/2020

Summary

Bug fixes and minor performance improvements.

New in this release

None

Resolved Issues

- Corrected image resize operator functionallity
- Compiler internal enhancements made that will benefit models such as BERT

Known issues and limitations

- See previous releases.

Other Notes

Dependencies

```
dmlc_nnvm-1.0.1826.0
dmlc_topi-1.0.1826.0
dmlc_tvm-1.0.1826.0
inferentia_hwm-1.0.897.0
islpy-2018.2
```

12.8.27 [1.0.6801.0]

Date 1/27/2020

Summary

Bug fixes and some performance enhancement related to data movement for BERT-type neural networks.

New in this release

None

Resolved Issues

- Improved throughput for operators processed in the Neuron Runtime CPU. As an example: execution of 4 single NeuronCore NEFF models of ResNet50 v2 float16 batch = 5 in parallel on an inf1.1xlarge sped up by 30%.
- Corrected shape handling in Gather(TensorFlow)/Take(MXNet) operators that are processed by the Neuron Runtime in the Neuron Runtime vCPU, which resolves a possible crash in Neuron Compiler when compiling models with these operators with some shapes.
- Added support for TensorFlow *OneHot* operator (as a Neuron Runtime CPU operator).
- Added more internal checking for compiler correctness with newly defined error messages for this case.

```
"Internal ERROR: Data race between Op1 'Name1(...) [...]' and Op2 'Name2(...) [...]'"
```

- Fixed out-of-memory issue introduced in 1.0.5939.0 such that some large models (BERT) compiled on instances with insufficient host memory would cause the runtime to crash with an invalid NEFF. This is actually a compiler error, but due to additional script layers wrapping this in the *Running TensorFlow BERT-Large with AWS Neuron*, this would have likely been seen as a runtime error like this:

```
2020-01-09 13:40:26.002594: E tensorflow/core/framework/op_segment.cc:54] Create kernel␣
↪failed: Invalid argument: neff is invalid
2020-01-09 13:40:26.002637: E tensorflow/core/common_runtime/executor.cc:642] Executor␣
↪failed to create kernel. Invalid argument: neff is invalid
[[{{node bert/NeuronOp}}]]
```

Known issues and limitations

See previous release notes. Some tutorials show use of specific compiler options and flags, these are needed to help provide guidance to the compiler to achieve best performance in specific cases. Please do not use in cases other than as shown in the specific tutorial as results may not be defined. These options should be considered experimental and will be removed over time.

Other Notes

Dependencies

```
dmlc_nnvm-1.0.1619.0
dmlc_topi-1.0.1619.0
dmlc_tvm-1.0.1619.0
inferentia_hwm-1.0.839.0
islpy-2018.2
```

12.8.28 [1.0.5939.0]

Date 12/20/2019

Summary

Bug fixes and some performance enhancement for NeuronCore Pipeline.

New in this release

Resolved Issues

- Fixed pipeline execution on more than 10 NeuronCores
- Improved NeuronCores Pipeline execution by improving data exchange efficiency between NeuronCores
- Added warning for unaligned memory access
- Fixed handling of cast on input FP32 tensor
- Improved handling of data layouts and transpose

- Improved dead-code elimination
- Improved efficiency of compute engine synchronization
- Improved efficiency of data transfers within the Neuron code

Known issues and limitations

See previous release notes. Some tutorials show use of specific compiler options and flags, these are needed to help provide guidance to the compiler to achieve best performance in specific cases. Please do not use in cases other than as shown in the specific tutorial as results may not be defined. These options should be considered experimental and will be removed over time.

Other Notes

Dependencies

- dmlc_nnvm-1.0.1416.0
- dmlc_topi-1.0.1416.0
- dmlc_tvm-1.0.1416.0
- inferentia_hwm-1.0.720.0
- islpy-2018.2

12.8.29 [1.0.5301.0]

Date 12/1/2019

Summary

New in this release

Resolved Issues

- Added warning for unsupported operators and convolution sizes
- Added warning for unsupported layout / upsampling
- Added support for Relu6, AddV2, BatchMatmulV2 operators
- Added support for default MXNet outputs in –io-config
- Improved performance of batched inference for convolutional networks
- Fixed MatMult column size 1
- Fixed bf16 constant loading
- Fixed Conv2D tile accumulation

Known Issues and Limitations

See previous release notes. Resolved issues are shown in Resolved Issues.

Other Notes

Please install g++ on AMIs without g++ pre-installed (i.e. server AMIs):

```
# Ubuntu
sudo apt-get install -y g++
```

```
# Amazon Linux
sudo yum nstall -y gcc-c++
```

Supported Python versions:

- 3.5, 3.6, 3.7

Supported Linux distributions:

- Ubuntu 16, Ubuntu 18, Amazon Linux 2

Dependencies

- dmlc_nnvm-1.0.1328.0
- dmlc_topi-1.0.1328.0
- dmlc_tvm-1.0.1328.0
- inferentia_hwm-1.0.674.0
- islpy-2018.2

12.8.30 [1.0.4680.0]

Date: 11/25/2019

New in this release

N/A, this is the first release.

Resolved issues

N/A, this is the first release.

Known issues and limitations

1. **Control flow** Inferentia has a limited support for control flow. In general, Neuron can only support control flow operators which are static at compile time, i.e. static length RNN, top-k, sort, …
2. **Size of neural network** The size of neural network is influenced by a) type of neural network (CNN, LSTM, MLP) , b) number of layers, c) sizes of input (dimension of the tensors, batch size, …). The current Neuron compiler release has a limitation in terms of the size of neural network it could effectively optimize. As a result, we limit CNN models (e.g. ResNet) to have an input size of up to 480x480 FP16, batch size of 4; LSTM models (e.g. GNMT) are limited to a time step limit of up to 900; MLP models (like BERT) are limited up to sequence-length equal 128, batch=8.
3. **Data layout** The Neuron compiler supports multiple data layout formats (NCHW, NHWC, …). Non-CNHW input/output data-layouts will require Neuron to insert additional *transpose* operations, causing a degradation in performance.
4. **Object detection models** Computer-vision object detection and segmentation models are not supported by the current release.
5. **Reduce data type** INT8 data type is not currently supported by the Neuron compiler.
6. **Tensor residency** When a sub-graph that is executed on the host is communicating with a sub-graph that is executing on Neuron cores, tensors are copied via the communication queues between the host and Inferentia memory for each inference, which may result in end-to-end performance degradation.
7. **Primary inputs in NeuronCore Pipeline mode** When a neural network is executed in NeuronCore Pipeline mode, only the first operator in a neural network can receive primary inputs from the host.

Other Notes

Dependencies

- nnvm: dmlc_nnvm-1.0.1219.0
- topi: dmlc_topi-1.0.1219.0
- tvm: dmlc_tvm-1.0.1219.0
- hwm: inferentia_hwm-1.0.602.0
- islpy: islpy-2018.2+aws2018.x.73.0

13.1.1 Neuron Monitor User Guide

Table of contents

- *Overview*
- *Using neuron-monitor*
  - *Configuration file example*
  - *Neuron applications tagging*
  - *JSON objects and fields in the configuration file*
  - *Neuron Runtime-level metric groups*
  - *System-wide metric groups*
- *Execution model*
- *The JSON output format*
- *Neuron application level metric groups*
  - *neuroncore_counters*
  - *execution_stats*
  - *memory_used*
  - *neuron_runtime_vcpu_usage*
- *System level metric groups*
  - *neuron_hw_counters*

- *vcpu_usage*
- *memory_info*

- *Companion scripts*
  - *neuron-monitor-cloudwatch.py*
  - *neuron-monitor-prometheus.py*

Overview

neuron-monitor collects metrics and stats from the Neuron Applications running on the system and streams the collected data to `stdout` in `JSON` format. It is provided as part of the `aws-neuron-tools` package.

These metrics and stats are organized into **metric groups** which can be configured by providing a configuration file as described in *Using neuron-monitor*

When running, **neuron-monitor** will:

- Collect the data for the metric groups which, based on the elapsed time since their last update, need to be updated
- Take the newly collected data and consolidate it into a large report
- Serialize that report to JSON and stream it to stdout from where it can be consumed by other tools - such as the sample *neuron-monitor-cloudwatch.py* and *neuron-monitor-prometheus.py* scripts.
- Wait until at least one **metric group** needs to be collected and repeat this flow

Using neuron-monitor

neuron-monitor CLI

neuron-monitor `[parameters]`

neuron-monitor accepts the following optional parameters:

- `--verbose` (int) default=0: Can be 0 to 4, and controls the amount of debugging and verbose information sent to stderr; **0: no output**, **4: maximum verbosity**
- `-c, --config-file` (string): Allows specifying a valid path to a neuron-monitor JSON configuration file

Example:

```
neuron-monitor -c monitor.conf
```

Not specifying any configuration file will enable collecting all the metric groups with a period of 5 seconds for all currently running Neuron applications.

Configuration file example

Example of a configuration file which enables all available **metric groups** for every running Neuron application, with a global update period of 1 second and sets an update period of 2 seconds for the `"neuron_hw_counters"` metric group:

```
{
  "period": "1s",
  "neuron_runtimes": [
    {
      "tag_filter": ".*",
      "metrics": [
        {
          "type": "neuroncore_counters"
        },
        {
          "type": "memory_used"
        },
        {
          "type": "neuron_runtime_vcpu_usage"
        },
        {
          "type": "execution_stats"
        }
      ]
    }
  ],
  "system_metrics": [
    {
      "type": "vcpu_usage"
    },
    {
      "type": "memory_info"
    },
    {
       "period": "2s",
       "type": "neuron_hw_counters"
    }
  ]
}
```

Neuron applications tagging

In order to make application monitoring easier, Neuron applications can be tagged with a 255 character string which identifies that app. Tagging is done using the `NEURON_PROCESS_TAG` environment variable.

For example: `NEURON_PROCESS_TAG=my_app_1 python training.py` will associate the `my_app_1` tag with that Python application. If `NEURON_PROCESS_TAG` is not specified, the application's PID will be used as a TAG.

This tag will be used by neuron-monitor to filter Neuron applications.

JSON objects and fields in the configuration file

- `"neuron_runtimes"` - array of objects specifying which Neuron Applications to monitor and what metric groups are enabled for each of them
  - `"tag_filter"` - a regex which will be used to filter Neuron applications tags in order to determine if they will be monitored (optional)
  - `"metrics"` - array of objects specifying which metric groups to capture for this Neuron application
    - `"type"` - type of metric group
- `"period"` - this field applies to **metric group** objects and sets the amount of time between two updates for that metric group
  - if can be specified as part of the **root** and/or **neuron_runtime** objects where it applies to all their children, and/or as part of a **metric group** object
  - if there's no period specified, a default value of **5 seconds** will be used
- `"system_metrics"` - array of objects specifying which system level metric groups are enabled

Neuron Runtime-level metric groups

- *neuroncore_counters* - NeuronCore related metrics
- *memory_used* - data on the amount of memory used by the Neuron application
- *vcpu_usage* - Neuron application vCPU utilization data
- *execution_stats* - Neuron application execution stats, including error count and latency

System-wide metric groups

- *vcpu_usage* - system-wide vCPU usage
- *memory_info* - system-wide memory usage
- *neuron_hw_counters* - counters for correctable and uncorrectable memory ecc events

Execution model

neuron-monitor waits for one or more **metric groups** to be up for update, then collects the corresponding data, consolidates it into a report which is streamed to stdout as a JSON and goes back to waiting.

The JSON output format

Whenever the report gets updated, a complete JSON is written to stdout. This is its structure:

```
{
  "neuron_runtime_data": [
    {
      "pid": 0,

      }
```

(continues on next page)

(continued from previous page)

```
    }
  ],
  "system_data": {
    "neuron_hw_counters": {
            [...]
    },
    "vcpu_usage": {
            [...]
    },
    "memory_info": {
            [...]
    }
  },
  "instance_info": {
            [...]
  },
  "neuron_hardware_info": {
            [...]
  }
}
```

- "neuron_runtime_data" is an array containing one entry per each Neuron application which passes the filter specified in the settings file
  - "pid" is the pid of this Neuron application
  - "neuron_runtime_tag" is the configured tag for the Neuron application
  - "error" specifies any error that occurred when collecting data from this Neuron application
  - "report" will contain the results for the Neuron application-level metric groups; their formats are described below
- "system_data" has a similar structure to "neuron_runtime_data"'s "report" but only contains system-level metric groups (not associated to any Neuron application)

Regardless of the configuration, the following two JSON objects are always present in the output:

instance_info Contains information about the instance on which neuron-monitor is running.

```
"instance_info": {
  "instance_name": "My_Instance",
  "instance_id": "i-0011223344556677a",
  "instance_type": "inf1.xlarge",
  "instance_availability_zone": "us-west-2b",
  "instance_availability_zone_id": "usw2-az2",
  "instance_region": "us-west-2",
  "ami_id": "ami-0011223344556677b",
  "subnet_id": "subnet-112233ee",
  "error": ""
}
```

Depending on when the instance was launched, the following fields might not be available:

- instance_availability_zone_id : available only for instances launched in 2020-08-24 and later
- instance_region : available only for instances launched on 2020-08-24 and later

- `instance_name` : available only if `instance_region` is set and aws-cli tools are installed

`error` will contain an error string if getting one of the fields, **except those mentioned above**, resulted in an error.

neuron_hardware_info Contains basic information about the Neuron hardware.

```
"neuron_hardware_info": {
  "neuron_device_count": 16,
  "neuroncore_per_device_count": 4,
  "error": ""
}
```

- `neuron_device_count` : number of available Neuron Devices
- `neuroncore_per_device_count` : number of NeuronCores present on each Neuron Device
- `error` : will contain an error string if any occurred when getting this information (usually due to the Neuron Driver not being installed or not running).

Each **metric group** requested in the settings file will get an entry in the resulting output. The general format for such an entry is:

```
"metric_group": {
  "period": 1.015, // Actual captured period, in seconds
  "error": "",     // Error, if any occurred, otherwise an empty string
  [...]            // Metric group specific data
}
```

Neuron application level metric groups

neuroncore_counters

```
"neuroncore_counters": {
  "period": 1.000113182,
  "neuroncores_in_use": {
    "0": {
      "neuroncore_utilization": 42.01,
    },
    "1": {
      "neuroncore_utilization": 42.02,
    },
    "2": {
      "neuroncore_utilization": 42.03,
    },
    "3": {
      "neuroncore_utilization": 42.04,
    }
  },
  "error": ""
}
```

- `"neuroncores_in_use"` is an object containing data for all the NeuronCores that were active when the data was captured, indexed by NeuronCore index: `"neuroncore_index": { neuroncore_data }`
  - `"neuroncore_utilization"` - NeuronCore utilization, in percent, during the captured period

- "error" - string containing any error that occurred when collecting the data

execution_stats

```
"execution_stats": {
  "period": 1.030613214,
  "error_summary": {
    "generic": 0,
    "numerical": 0,
    "transient": 0,
    "model": 0,
    "runtime": 0,
    "hardware": 0
  },
  "execution_summary": {
    "completed": 123,
    "completed_with_err": 0,
    "completed_with_num_err": 0,
    "timed_out": 0,
    "incorrect_input": 0,
    "failed_to_queue": 0
  },
  "latency_stats": {
    "total_latency": {
      "p0": 0.01100001,
      "p1": 0.01100002,
      "p25": 0.01100004,
      "p50": 0.01100008,
      "p75": 0.01100010,
      "p99": 0.01100012,
      "p100": 0.01100013
    },
    "device_latency": {
      "p0": 0.01000001,
      "p1": 0.01000002,
      "p25": 0.01000004,
      "p50": 0.01000008,
      "p75": 0.01000010,
      "p99": 0.01000012,
      "p100": 0.01000013
    }
  },
  "error": ""
},
```

- "error_summary" is an object containing the error counts for the captured period indexed by their type
  - "generic" - generic execution errors
  - "numeric" - NAN errors encountered during execution
  - "transient" - recoverable errors, such as ECC corrections
  - "model" - model-related errors

  - "runtime" - Neuron Runtime errors
  - "hardware" - hardware errors such as uncorrectable ECC issues

- "execution_summary" is an object containing all execution outcome counts for the captured period indexed by their type
  - "completed" - executions completed successfully
  - "completed_with_err" - executions that ended in an error other than a numeric error
  - "completed_with_num_err" - executions that ended in a numeric error
  - "timed_out" - executions that took longer than the Neuron Runtime configured timeout value
  - "incorrect_input" - executions that failed to start due to incorrect input being provided
  - "failed_to_queue" - execution requests that were rejected due to Neuron Runtime not being able to queue them
- "latency_stats" contains two objects containing latency percentiles, in seconds, for the data captured for the model executed during the captured period. If there are no models being executed during this time, the two objects will be null (i.e. "total_latency": null)
  - "total_latency" - percentiles, in seconds, representing

  latency for an execution as measured by the Neuron Runtime - "device_latency" - percentiles, in seconds, representing execution time exclusively on the Neuron Device
- "error" - string containing any error that occurred when collecting the data

memory_used

```
"memory_used": {
  "period": 1.00001,
  "neuron_runtime_used_bytes": {
    "host": 6997643264,
    "neuron_device": 12519788544,

        }
      }
    },
    ...
    ],
    "error": ""
}
```

- "memory_used" summarizes the amount of memory used by the Neuron application
  - "neuron_runtime_used_bytes" - current amount of memory used by the Neuron application
    - "host" - total host DRAM usage in bytes
    - "neuron_device" - total Neuron device memory usage in bytes
    - "usage_breakdown" - a breakdown of the total memory usage in the other two fields
      - "host" - breakdown of the host memory usage
      - "application_memory" - amount of host memory used by the application - this includes all allocations that are not included in the next categories

- "constants" - amount of host memory used for constants during training (or weights during inference)
- "dma_buffers" - amount of host memory used for DMA transfers
- "tensors" - amount of host memory used for tensors
- "neuroncore_memory_usage" - a breakdown of memory allocated on the Neuron Devices and the NeuronCores for which it was allocated

"0" - "32" (for trn1-32xlarge) - NeuronCores for which the memory was allocated

"constants" - amount of device memory used for constants during training (or weights during inference)

"model_code" - amount of device memory used for models' executable code

"model_shared_scratchpad" - amount of device memory used for the scratchpad shared by the models - a memory region reserved for the models'

internal variables and auxiliary buffers - "runtime_memory" - amount of device memory used by the Neuron Runtime - "tensors" - amount of device memory used for tensors

- "loaded_models" - array containing objects representing loaded models
  - "name" - name of the model
  - "uuid" - unique id for the model
  - "model_id" - Neuron application-assigned ID for this model
  - "is_running" - true if this model is currently started, false otherwise
  - "subgraphs" - object containing all the subgraphs for the model, indexed by their name: "subgraph_name": { subgraph_data }
    - "memory_used_bytes" - memory usage for this subgraph
      - "host" - total host DRAM usage in bytes
      - "neuron_device" - total Neuron device DRAM usage in bytes
      - "usage_breakdown" - a breakdown of memory allocated at load time for this model
      - "host" - breakdown of host memory allocated for this model
      - "application_memory" - amount of host memory allocated for this model by the Neuron Runtime which doesn't fall in any of the next categories
      - "constants" - amount of host memory used for constants during training (or weights during inference)
      - "dma_buffers" - host memory allocated for DMA transfers for this model
      - "tensors" - amount of device memory used for tensors at model load time
      - "neuron_device" - a breakdown of device memory allocated for this model
      - "constants" - amount of device memory used for constants during training (or weights during inference)
      - "model_code" - amount of device memory used for the model's executable code
      - "runtime_memory" - amount of device memory used by the Neuron Runtime for this model
      - "tensors" - amount of device memory allocated for tensors at this model's load time

        * "neuroncore_index" - NeuronCore index on which the subgraph is loaded
        * "neuron_device_index" - Neuron device index on which the subgraph is loaded

- "error" - string containing any error that occurred when collecting the data

neuron_runtime_vcpu_usage

```
"neuron_runtime_vcpu_usage": {
  "period": 1.030604818,
  "vcpu_usage": {
    "user": 42.01,
    "system": 12.34
  },
  "error": ""
}
```

- "vcpu_usage" - object showing vCPU usage in percentages for the Neuron application during the captured period
  - "user" - percentage of time spent in user code by this Neuron Application
  - "system" - percentage of time spent in kernel code by this Neuron application
- "error" - string containing any error that occurred when collecting the data

System level metric groups

neuron_hw_counters

```
"neuron_hw_counters": {
  "period": 1.030359284,
  "neuron_devices": [
    {
      "neuron_device_index": 0,
      "mem_ecc_corrected": 0,
      "mem_ecc_uncorrected": 0,
      "sram_ecc_uncorrected": 0,
      "sram_ecc_corrected": 0
    }
  ],
  "error": ""
},
```

- "neuron_devices" - array containing ECC data for all Neuron devices
  - "neuron_device_index" - Neuron device index
  - "mem_ecc_corrected" - number of corrected ECC events in the Neuron device's DRAM
  - "mem_ecc_uncorrected" - number of uncorrected ECC events in the Neuron device's DRAM
  - "sram_ecc_uncorrected" - number of uncorrected ECC events in the Neuron device's SRAM
  - "sram_ecc_corrected" - number of corrected ECC events in the Neuron device's SRAM
- "error" - string containing any error that occurred when collecting the data

vcpu_usage

```
"vcpu_usage": {
  "period": 0.999974868,
  "average_usage": {
    "user": 32.77,
    "nice": 0,
    "system": 22.87,
    "idle": 39.36,
    "io_wait": 0,
    "irq": 0,
    "soft_irq": 0
  },
  "usage_data": {
    "0": {
      "user": 34.41,
      "nice": 0,
      "system": 27.96,
      "idle": 37.63,
      "io_wait": 0,
      "irq": 0,
      "soft_irq": 0
    },
    "1": {
      "user": 56.84,
      "nice": 0,
      "system": 28.42,
      "idle": 14.74,
      "io_wait": 0,
      "irq": 0,
      "soft_irq": 0
    },
    [...]
  },
  "context_switch_count": 123456,
  "error": ""
}
```

- each vCPU usage object contains the following fields:
  - `"user"` - percentage of time spent in user code
  - `"nice"` - percentage of time spent executing niced user code
  - `"system"` - percentage of time spent executing kernel code
  - `"idle"` - percentage of time spent idle
  - `"io_wait"` - percentage of time spent waiting for IO operations
  - `"irq"` - percentage of time spent servicing hardware interrupts
  - `"soft_irq"` - percentage of time spent servicing software interrupts
- `"average_usage"` - contains the average usage across all vCPUs during the captured period
- `"usage_data"` - contains per vCPU usage during the captured period

- "context_switch_count" - contains the number of vCPU context switches during the captured period
- "error" - string containing any error that occurred when collecting the data

memory_info

```
"memory_info": {
  "period": 5.346411129,
  "memory_total_bytes": 49345835008,
  "memory_used_bytes": 16042344448,
  "swap_total_bytes": 0,
  "swap_used_bytes": 0,
  "error": ""
}
```

- "memory_total_bytes" - total size of the host memory, in bytes
- "memory_used_bytes" - amount of host memory in use, in bytes
- "swap_total_bytes" - total size of the host swap file, in bytes
- "swap_used_bytes" - amount of swap memory in use, in bytes

Companion scripts

neuron-monitor is installed with two example Python companion script: *neuron-monitor-cloudwatch.py* and *neuron-monitor-prometheus.py*.

neuron-monitor-cloudwatch.py

It requires Python3 and the boto3 Python module. It is installed to: `/opt/aws/neuron/bin/neuron-monitor-cloudwatch.py`.

Using neuron-monitor-cloudwatch.py

```
neuron-monitor | neuron-monitor-cloudwatch.py --namespace <namespace> --region <region>
```

For example:

```
neuron-monitor | neuron-monitor-cloudwatch.py --namespace neuron_monitor_test --region␣
↪us-west-2
```

neuron-monitor-prometheus.py

It requires Python3 and the Prometheus client Python module. It is installed to: `/opt/aws/neuron/bin/neuron-monitor-prometheus.py`.

Using neuron-monitor-prometheus.py

```
neuron-monitor | neuron-monitor-prometheus.py --port <port>
```

For example:

```
neuron-monitor | neuron-monitor-prometheus.py --port 8008
```

The default value for `--port` is `8000`.

If your data visualization framework is Grafana, we provided a Grafana dashboard which integrates with Prometheus and this script.

13.1.2 Neuron Top User Guide

Table of contents

- *Overview*
- *Using neuron-top*
  - *Command line arguments*
  - *User interface*

Overview

`neuron-top` provides useful information about NeuronCore and vCPU utilization, memory usage, loaded models, and Neuron applications.

Note: If you are parsing `neuron-top` output in your automation environment, you can now replace it with `neuron-monitor` (*Neuron Monitor User Guide*) which outputs data in a standardized, easier to parse JSON format.

Using neuron-top

Command line arguments

Launch `neuron-top` by simply typing its name in the shell: `neuron-top`.

User interface

The user interface is divided in 4 sections. The data shown in these sections applies to the currently selected tab - which can be the 'all' tab, which aggregates data from all running Neuron processes, or a tab representing a single Neuron process:

- The `Neuroncore Utilization` section shows the NeuronCore utilization for the currently selected tab
- The `VCPU Utilization` section shows:
  - `System vCPU usage` - the two percentages are user% and system%
  - `Runtime vCPU usage` - same breakdown
- The `Memory Usage Summary` section provides a breakdown of the total memory usage on the Neuron Device as well as on the host:
  - `Host Used Memory` - amount of host memory used by the selected application (or an aggregate of all applications if 'All' is selected)
    - `Total` - total amount of host memory used

    * `Tensors` - amount of host memory used for tensors
    * `Constants` - amount of host memory used for constants (for applications running training) or weights (for applications running inferences)
    * `DMA Buffers` - amount of host memory used for DMA transfers
    * `App. Memory` - amount of host memory used by the application that doesn't fall in any of the previous categories
  - `Device Used Memory` - amount of device memory used by the selected application (or an aggregate of all applications if 'All' is selected)
    * `Total` - total amount of device memory used
    * `Tensors` - amount of device memory used for tensors
    * `Constants` - amount of device memory used for constants (for applications running training) or weights (for applications running inferences)
    * `Model Code` - amount of device memory used for storing model executable code
    * `Runtime Memory` - amount of device memory used by the Neuron Runtime (outside of the previous categories)
    * `Model Scratchpad` - amount of device memory used for the shared model scratchpad, a shared buffer used for internal model variables and other auxiliary buffers

- `Memory Usage Details` contains memory usage data organized as a tree which can be expanded/collapsed. The columns are:
  - `Model ID` - the Neuron Runtime identifier for this model instance
  - `Host Memory` - amount of host memory used
  - `Device Memory` - amount of device memory used

The tree view shows the amount of memory used for the same categories shown in the `Memory Usage Summary` but in this section they are attached to either a model (if the memory has been allocated at model load time for that model), or to a NeuronCore (if the memory can't be associated with a model, but has been allocated for that NeuronCore). The 'parent' shows the total amount of memory used - the sum of its children.

Note: The up/down/left/right keys can be used to navigate the tree view. The 'x' key expands/collapses the entire tree.

The bottom bar shows which Neuron process' data is currently displayed by highlighting its tag using a green font and marking it using a pair of '>', '<' characters. The 'all' tab shows an aggregated view of all the Neuron processes currently running on the instance.

Note: The '1'-'9' keys select the current tab.'a'/'d' selects the previous/next tab on the bar.

This document is relevant for: `Inf1`, `Trn1`

This document is relevant for: `Inf1`, `Trn1`

13.1.3 Neuron LS User Guide

To identify number of Neuron Devices in a given instance use the `neuron-ls` command. `neuron-ls` will also show which processes are using each Device, including the command used to launch each of those processes.

neuron-ls CLI

neuron-ls [options]

Available options:

- `--wide, -w`: Displays the table in a wider format.
- `--show-all-procs, -a`: Show all processes using the Neuron Devices, including processes that aren't using Neuron Runtime 2.x such as `neuron-monitor` or `neuron-ls` itself.
- `--topology, -t`: Display topology information about the system's Neuron Devices.

Note: If you're running Neuron Runtime 1.x `neuron-rtd` daemons, use `sudo` with the `neuron-ls` command to obtain their address and version information. Without `sudo`, the `neuron-rtd` processes will be considered generic processes using one or more Devices and will only be displayed when running `neuron-ls` with the `--show-all-procs` option.

Examples

First we will show the output of `neuron-ls` on an Inf1.6xlarge instance.

```
$ neuron-ls

Neuron Tools [2.6.0.0]

Date: 12/09/2022

This release adds support for profiling with the Neuron Plugin for TensorBoard on TRN1. Please check out the documentation *Neuron Plugin for TensorBoard (Trn1)*.

New in the release:

- Updated profile post-processing for workloads executed on TRN1

Neuron Tools [2.5.19.0]

Date: 11/07/2022

New in the release:

- Minor bug fixes and improvements.

Neuron Tools [2.5.16.0]

Date: 10/26/2022

New in the release:

- New `neuron-monitor` and `neuron-top` feature: **memory utilization breakdown**. This new feature provides more details on how memory is being currently used on the Neuron Devices as well as on the host instance.
- `neuron-top`'s UI layout has been updated to accommodate the new **memory utilization breakdown** feature.
- `neuron-monitor`'s `inference_stats` metric group was renamed to `execution_stats`. While the previous release still supported `inference_stats`, starting this release the name `inference_stats` is considered deprecated and can't be used anymore.

Note: For more details on the new **memory utilization breakdown** feature in `neuron-monitor` and `neuron-top` check out the full user guides: *Neuron Monitor User Guide* and *Neuron Top User Guide*.

Bug Fixes:

- Fix a rare crash in `neuron-top` when the instance is under heavy CPU load.
- Fix process names on the bottom tab bar of `neuron-top` sometimes disappearing for smaller terminal window sizes.

Neuron Tools [2.4.6.0]

Date: 10/10/2022

This release adds support for both EC2 INF1 and TRN1 platforms. Name of the package changed from aws-neuron-tools to aws-neuronx-tools. Please remove the old package before installing the new one.

New in the release:

- Added support for ECC counters on Trn1
- Added version number output to neuron-top
- Expanded support for longer process tags in neuron-monitor.
- Removed hardware counters from the default neuron-monitor config to avoid sending repeated errors - will add back in future release.
- `neuron-ls` - Added option `neuron-ls --topology` with ASCII graphics output showing the connectivity between Neuron Devices on an instance. This feature aims to help in understanding pathways between Neuron Devices and in exploiting code or data locality.

Bug Fixes:

- Fix neuron-monitor and neuron-top to show the correct Neuron Device when running in a container where not all devices are present.

Neuron Tools [2.1.4.0]

Date: 04/29/2022

- Minor updates

Neuron Tools [2.0.790.0]

Date: 03/25/2022

- `neuron-monitor`: fixed a floating point error when calculating CPU utilization.

Neuron Tools [2.0.623.0]

Date: 01/20/2022

New in the release:

- `neuron-top` - Added "all" tab that aggregates all aggregate all running Neuron processes into a single view.
- `neuron-top` - Improved startup time to approximately 1.5 seconds in most cases.
- `neuron-ls` - Removed header message about updating tools from neuron-ls output

Bug fixes:

- `neuron-top` - Reduced single CPU core usage down to 0.7% from 80% on inf1.xlarge when running `neuron-top` by switching to an event-driven approach for screen updates.

Neuron Tools [2.0.494.0]

Date: 12/27/2021

- Security related updates related to log4j vulnerabilities.

Neuron Tools [2.0.327.0]

Date: 11/05/2021

- Updated Neuron Runtime (which is integrated within this package) to `libnrt 2.2.18.0` to fix a container issue that was preventing the use of containers when /dev/neuron0 was not present. See details here neuron-runtime-release-notes.

Neuron Tools [2.0.277.0]

Date: 10/27/2021

New in this release:

- Tools now support applications built with Neuron Runtime 2.x (`libnrt.so`).

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.
  - Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

- Updates have been made to `neuron-ls` and `neuron-top` to significantly improve the interface and utility of information provided.
- Expands `neuron-monitor` to include additional information when used to monitor latest Frameworks released with Neuron 1.16.0.

  neuron_hardware_info Contains basic information about the Neuron hardware.

```
"neuron_hardware_info": {
   "neuron_device_count": 16,
   "neuroncore_per_device_count": 4,
   "error": ""
}
```

  - `neuron_device_count` : number of available Neuron Devices
  - `neuroncore_per_device_count` : number of NeuronCores present on each Neuron Device
  - `error` : will contain an error string if any occurred when getting this information (usually due to the Neuron Driver not being installed or not running).

- `neuron-cli` entering maintenance mode as it's use is no longer relevant when using ML Frameworks with an integrated Neuron Runtime (libnrt.so). see maintenance_mxnet_1_5 for more information.

Track Training Progress in TensorBoard using PyTorch Neuron

Table of Contents

- *Multi-layer perceptron MNIST model*
- *Output TensorBoard logs*
- *View loss in TensorBoard*

This tutorial explains how to track training progress in TensorBoard while running a multi-layer perceptron MNIST model on Trainium using PyTorch Neuron.

Multi-layer perceptron MNIST model

This tutorial is based on the MNIST example for PyTorch Neuron on Trainium. For the full tutorial, please see *Multi-Layer Perceptron Training Tutorial*.

Output TensorBoard logs

To generate TensorBoard logs, we first modify the training script to use the `SummaryWriter`:

```
from torch.utils.tensorboard import SummaryWriter
writer = SummaryWriter('./output')
```

In the training loop, we can then use the `add_scalar` API to log the loss per step.

```
writer.add_scalar("step loss", loss, idx)
```

At the end of the script, add `writer.flush()` to ensure all logs are written.

Save the following code as `train_tb.py` and run it as `python3 train_tb.py` on a Trn1 instance. The generated logs can be found in the `./output` directory that was passed to `SummaryWriter`.

```
import os
import time
import torch
import torch.nn as nn
import torch.nn.functional as F

from torchvision.datasets import mnist
from torch.optim import SGD
from torch.utils.data import DataLoader
from torchvision.transforms import ToTensor

# XLA imports
import torch_xla.core.xla_model as xm

from torch.utils.tensorboard import SummaryWriter

# Declare 3-layer MLP for MNIST dataset
class MLP(nn.Module):
  def __init__(self, input_size = 28 * 28, output_size = 10, layers = [120, 84]):
      super(MLP, self).__init__()
      self.fc1 = nn.Linear(input_size, layers[0])
      self.fc2 = nn.Linear(layers[0], layers[1])
      self.fc3 = nn.Linear(layers[1], output_size)

  def forward(self, x):
      x = F.relu(self.fc1(x))
      x = F.relu(self.fc2(x))
      x = self.fc3(x)
      return F.log_softmax(x, dim=1)

# Load MNIST train dataset
train_dataset = mnist.MNIST(root='./MNIST_DATA_train', \
```

(continues on next page)

(continued from previous page)

```
                                train=True, download=True, transform=ToTensor())

def main():
    # Prepare data loader
    train_loader = DataLoader(train_dataset, batch_size=32)

    # Fix the random number generator seeds for reproducibility
    torch.manual_seed(0)

    # XLA: Specify XLA device (defaults to a NeuronCore on Trn1 instance)
    device = 'xla'

    # Move model to device and declare optimizer and loss function
    model = MLP().to(device)
    optimizer = torch.optim.SGD(model.parameters(), lr=0.01)
    loss_fn = torch.nn.NLLLoss()

    # Use SummaryWriter to generate logs for TensorBoard
    writer = SummaryWriter('./output')

    # Run the training loop
    print('----------Training ---------------')
    model.train()
    start = time.time()
    for idx, (train_x, train_label) in enumerate(train_loader):
        optimizer.zero_grad()
        train_x = train_x.view(train_x.size(0), -1)
        train_x = train_x.to(device)
        train_label = train_label.to(device)
        output = model(train_x)
        loss = loss_fn(output, train_label)
        writer.add_scalar("step loss", loss, idx) # add the step loss to the TensorBoard␣
↪logs
        loss.backward()
        optimizer.step()
        xm.mark_step() # XLA: collect ops and run them in XLA runtime
        if idx < 2: # skip warmup iterations
            start = time.time()

    # Compute statistics
    interval = idx - 2 # skip warmup iterations
    throughput = interval / (time.time() - start)
    print("Train throughput (iter/sec): {}".format(throughput))
    print("Final loss is {:0.4f}".format(loss.detach().to('cpu')))

    # Ensure TensorBoard logs are all written
    writer.flush()

    # Save checkpoint for evaluation
    os.makedirs("checkpoints", exist_ok=True)
    checkpoint = {'state_dict': model.state_dict()}
    # XLA: use xm.save instead of torch.save to ensure states are moved back to cpu
```

(continues on next page)

(continued from previous page)

```
    # This can prevent "XRT memory handle not found" at end of test.py execution
    xm.save(checkpoint,'checkpoints/checkpoint.pt')

    print('----------End Training ---------------')

if __name__ == '__main__':
    main()
```

View loss in TensorBoard

In order to view your training metrics, install TensorBoard in your Python environment:

```
pip install tensorboard
```

Then, launch TensorBoard with the `./output` directory

```
tensorboard --logdir ./output
```

Once running, open a new SSH connection to the instance and port-forward TCP port 6006 (ex: -L 6006:127.0.0.1:6006). Once the tunnel is established, TensorBoard can then be accessed via web browser at the following URL: http://localhost:6006. Please note that you will not be able to access TensorBoard if you disconnect your port-forwarding SSH session to the Trainium instance.

In TensorBoard, you can now see the loss per step plotted. When capturing loss for multiple runs, you can plot them together on the same graph to compare runs. Be sure to change the output directory for different runs, for example `./output/run1` for the first, `./output/run2` for the second, etc.

Neuron Plugin for TensorBoard (Trn1)

Table of Contents

- *Overview*
- *Enable profiling on Trn1*
- *Launch TensorBoard*
- *View results in TensorBoard*
- *Neuron Trace View*
- *Neuron Operator View*
- *Neuron Operator Timeline View*

Overview

This guide is for developers who want to better understand how their model is executed using Neuron SDK through TensorBoard.

The Neuron plugin for TensorBoard provides metrics to the performance of machine learning tasks accelerated using the Neuron SDK. It is compatible with TensorBoard versions 1.15 and higher. It provides visualizations and profiling results for graphs executed on NeuronCores.

Note: The following information is compatible with Neuron SDK for Trn1. For a walkthrough on Inf1, please check out the guide *Neuron Plugin for TensorBoard (Inf1)*.

Enable profiling on Trn1

Note: Profiling is currently only supported with PyTorch Neuron (`torch-neuronx`).

Please refer to the following guides:

- **PyTorch-Neuron**
  - torch-neuronx-profiling-with-tb

Launch TensorBoard

In this step, we will process the Neuron profile data and launch TensorBoard.

1. Install the Neuron plugin for Tensorboard on your EC2 instance.

```
python -m pip config set global.extra-index-url "https://pip.repos.neuron.amazonaws.com"

pip install tensorboard-plugin-neuronx
```

Note: If using TensorBoard >= 2.5, please use the `--load_fast=false` option when launching. `tensorboard --logdir results --load_fast=false`

2. After you see the following message, TensorBoard is ready to use. By default, TensorBoard will be launched at `localhost:6006`.

```
...
Serving TensorBoard on localhost; to expose to the network, use a proxy or pass --bind_
↪all
TensorBoard 2.4.1 at http://localhost:6006/ (Press CTRL+C to quit)
```

View results in TensorBoard

In this step, we will view the Neuron plugin for TensorBoard from a browser on your local development machine.

1. Connect to the EC2 instance where TensorBoard is running while enabling port forwarding. In this example, we assume TensorBoard has been launched using the default address `localhost:6006`.

```
# if Ubuntu-based AMI
ssh -i <PEM key file> ubuntu@<instance DNS> -L 6006:localhost:6006

# if AL2-based AMI
ssh -i <PEM key file> ec2-user@<instance DNS> -L 6006:localhost:6006
```

2. In a browser, visit .

3. In the top navigation bar, switch from `Graphs` to `Neuron`. If it does not show up, please wait a while and refresh the page while the plugin loads. If the issue persists, check the `Inactive` dropdown list on the right and check for `Neuron`.

4. If TensorBoard failed to find the generated logs, you will see the following message:

In this case, please make sure the version of the `aws-neuronx-tools` package and the Neuron framework package is

from Neuron release 2.6 or newer.

Neuron Trace View

The trace view gives a high level timeline of execution by aligning Neuron events, such as Neuron Device execution, data transfers, and Collective Compute synchronization (if applicable), with other events from the XLA profiler.

Use this view to better understand bottlenecks during the run, and potentially experiment with how execution changes by moving the `mark_step()` call which will execute the graph.

Neuron Operator View

The operator view can show timing information for both the framework operators and HLO operators by selecting the `operator-framework` and `operator-hlo` tools respectively. The pie charts show breakdowns of the time taken by device, as well as per operator on a single device. The table below lists out the operators and can be sorted by clicking on the columnn headers. For fused operations, hover over the `?` to see which operators are being executed.

For a quick glance at the most time consuming operators, click the `Time %` column in the table to sort by the relative time spent on this type of operation compared to the rest of the model.

Neuron Operator Timeline View

The operator timeline view is a detailed look into a single execution with Neuron. Compute and data transfers are shown as two separate processes, with each showing a hierarchical view of the framework operators and their correspondingg HLO operation. The fused operations can be a result of compiler optimizations or are operations that are running in parallel on the device. Each bar can be clicked to show information regarding which operators are overlapped.

This view can give better insight into how operators translate to Neuron, as well as how certain Neuron compiler options may improve performance.

Known Issues and Limitations - Updated 11/29/2022

The following are not limitations in the Neuron plugin, but may affect your ability to use TensorBoard.

- The Neuron plugin for Trn1 (`tensorboard-plugin-neuronx`) is not compatible with the Neuron plugin for Inf1 (`tensorboard-plugin-neuron`). Please ensure you only have only the correct package installed.

Neuron Plugin for TensorBoard release [2.5.0.0]

Date: 12/09/2022

Summary

- Added support for PyTorch Neuron on Trn1 (`torch-neuronx`) with new views! Includes a trace view, an operator view, and an operator timeline view. For more info, check out the documentation *Neuron Plugin for TensorBoard (Trn1)*.

  Important:

  - You must update to the latest Neuron Tools (`aws-neuronx-tools` version 2.6 or newer) and install `tensorboard-plugin-neuronx` for proper functionality of the Neuron plugin on Trn1.
  - For Inf1, please continue to use `tensorboard-plugin-neuron`. Refer to the getting started guide on Inf1 *Neuron Plugin for TensorBoard (Inf1)*.

Neuron Plugin for TensorBoard release [2.4.0.0]

Date: 04/29/2022

Summary

- Minor updates.

Neuron Plugin for TensorBoard release [2.3.0.0]

Date: 03/25/2022

Summary

- Minor updates.

Neuron Plugin for TensorBoard release [2.2.0.0]

Date: 10/27/2021

New in this release

- Neuron Plugin for TensorBoard now support applications built with Neuron Runtime 2.x (`libnrt.so`).

  Important:

  - You must update to the latest Neuron Driver (`aws-neuron-dkms` version 2.1 or newer) for proper functionality of the new runtime library.
  - Read *Introducing Neuron Runtime 2.x (libnrt.so)* application note that describes *why are we making this change* and how *this change will affect the Neuron SDK* in detail.
  - Read *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for detailed information of how to migrate your application.

[2.1.2.0]

Date: 8/12/2021

Summary

- Adds support for Neuron Tensorflow 2.5+

[2.1.0.0]

Date: 5/28/2021

Summary

- No major changes or fixes. Released with other Neuron packages.

[2.0.29.0]

Date: 4/30/2021

Summary

- First release Neuron plugin for TensorBoard. Check out it out here: *Neuron Plugin for TensorBoard (Inf1)*.
  - The Neuron plugin is now compatible with TensorBoard 2.0 and higher, in addition to TensorBoard 1.15
  - Provides a centralized place to better understand execution using Neuron SDK.
  - Continues support visualization for TensorFlow graphs, with support for PyTorch and MXNet coming in future releases.
- Neuron plugin for TensorBoard is supported for Neuron tools >= 1.5, which is first introduced in Neuron v1.13.0 release
- TensorBoard-Neuron is deprecated, and only supported for Neuron tools <= 1.4.12.0. The final version, 1.4.12.0 is part of Neuron v1.12.2 release.

[1.15.0.1.2.6.0]

Date: 2/24/2021

Summary

- Fix for CVE-2021-3177.

[1.15.0.1.1.1.0]

Date: 12/23/2020

Summary

- Minor internal improvements.

[1.15.0.1.0.615.0]

Date: 11/17/2020

Summary

- Fix issue with viewing chrome trace in Neuron profile plugin in Chrome 80+.

Resolved Issues

- Updated dependencies to polyfill missing APIs used by chrome trace in newer browser versions.

[1.15.0.1.0.600.0]

Date: 09/22/2020

Summary

- Minor internal improvements.

[1.15.0.1.0.570.0]

Date: 08/08/2020

Summary

- Minor internal improvements.

[1.15.0.1.0.513.0]

Date: 07/16/2020

Summary

- Minor internal improvements.

[1.15.0.1.0.491.0]

Date 6/11/2020

Summary

Fix issue where utilization was missing in the op-profile view.

Resolved Issues

- The op-profile view in the Neuron Profile plugin now correctly shows the overall NeuronCore utilization.

[1.15.0.1.0.466.0]

Date 5/11/2020

Summary

Fix potential installation issue when installing both tensorboard and tensorboard-neuron.

Resolved Issues

- Added tensorboard as a dependency in tensorboard-neuron. This prevents the issue of overwriting tensorboard-neuron features when tensorboard is installed after tensorboard-neuron.

Other Notes

[1.15.0.1.0.392.0]

Date 3/26/2020

Summary

Added ability to view CPU node latency in the Graphs plugin and the Neuron Profile plugins.

Major New Features

- Added an aggregate view in addition to the current Neuron subgraph view for both the Graphs plugin and the Neuron Profile plugin.
- When visualizing a graph executed on a Neuron device, CPU node latencies are available when coloring the graph by "Compute time" using the "neuron_profile" tag.
- The Neuron Profile plugin now has an overview page to compare time spent on Neuron device versus on CPU.

Other Notes

- Requires Neuron-RTD config option "enable_node_profiling" to be set to "true"

[1.15.0.1.0.366.0]

Date 02/27/2020

Summary

Reduced load times and fixed crashes when loading large models for visualization.

Resolved Issues

- Enable large attribute filtering by default
- Reduced load time for graphs with attributes larger than 1 KB
- Fixed a fail to load graphs with many large attributes totaling more than 1 GB in size

[1.15.0.1.0.315.0]

Date 12/20/2019

Summary

No major chages or fixes. Released with other Neuron packages.

[1.15.0.1.0.306.0]

Date 12/1/2019

Summary

Major New Features

Resolved Issues

Known Issues & Limits

Same as prior release

Other Notes

[1.15.0.1.0.280.0]

Date 11/29/2019

Summary

Initial release packaged with DLAMI.

Major New Features

N/A, initial release.

See user guide here: https://github.com/aws/aws-neuron-sdk/blob/master/docs/neuron-tools/getting-started-tensorboard-neuron.md

Resolved Issues

N/A - first release

Known Issues & Limits

- Must install TensorBoard-Neuron by itself, or after regular TensorBoard is installed. If regular Tensorboard is installed after TensorBoard-Neuron, it may overwrite some needed files.
- Utilization missing in Op Profile due to missing FLOPs calculation (see overview page instead)
- Neuron Profile plugin may not immediately show up on launch (try reloading the page)
- Graphs with NeuronOps may take a long time to load due to attribute size
- Instructions that cannot be matched to a framework layer/operator name show as “” (blank)
- CPU Usage section in chrome-trace is not applicable

- Debugger currently supports TensorFlow only
- Visualization requires a TensorFlow-compatible graph

Other Notes

This document is relevant for: `Inf1`, `Trn1`

13.2.2 TensorBoard for Inf1

This document is relevant for: `Inf1`

Neuron Plugin for TensorBoard (Inf1)

  - *See performance summary*
  - *Get a breakdown of time spent per NeuronCore*
  - *Get a breakdown of time spent per operator*

Overview

This guide is for developers who want to better understand how their model is executed using Neuron SDK through TensorBoard.

The Neuron plugin for TensorBoard provides metrics to the performance of machine learning tasks accelerated using the Neuron SDK. It is compatible with TensorBoard versions 1.15 and higher. It provides visualizations and profiling results for graphs executed on NeuronCores.

Note: The following information is compatible with Neuron SDK for Inf1. For a walkthrough on the latest version, please check out the guide *Neuron Plugin for TensorBoard (Trn1)*.

Note: Graph visualization is currently only supported for TensorFlow-Neuron. Support for MXNet-Neuron and PyTorch-Neuron visualization will be added in a future release.

Compile the neural network

3. Refer to the following guides on how to compile a graph using Neuron SDK.

- **TensorFlow-Neuron**
  - *Running ResNet50 on Inferentia*
- **PyTorch-Neuron:**
  - "Compile model for Neuron" in *PyTorch-Neuron Resnet50 Tutorial*
- **MXNet-Neuron:**
  - *Running Neuron Apache MXNet (Incubating) ResNet50 on Inferentia*

Enable profiling

In this step, we enable Neuron profile data collection and collect results from executing an inference.

4.1. To start profiling the neural network and collect inference traces, create a directory where profile data will be dumped and set the `NEURON_PROFILE` environment variable. In this example, we will assume this directory is `$HOME/profile`

```
mkdir -p $HOME/profile
export NEURON_PROFILE=$HOME/profile
```

4.2. Ensure Neuron Tools are executable by setting the `PATH` environment variable.

```
export PATH=/opt/aws/neuron/bin:$PATH
```

4.3. Execute inference!

Note: Please run the inference script outside of Jupyter notebook. Profiling in Jupyter notebook is not supported at this time.

Note: Please ensure the inference script executes only one inference, as profiling results are currently only supported for a single inference.

For more info on how to execute inference, refer to the following guides:

- **TensorFlow-Neuron**
  - *Running ResNet50 on Inferentia*

- **PyTorch-Neuron**
  - "Run inference on Single Core" in *ResNet50 model for Inferentia*
- **MXNet-Neuron**
  - *Running Neuron Apache MXNet (Incubating) ResNet50 on Inferentia*

4.4. Check if profiling results were successfully saved. In the directory pointed to by `NEURON_PROFILE` environment variable set in Step 4.1, there should be at least two files, one with the `.neff` extension and one with the `.ntff` extension. For TensorFlow-Neuron users, the graph file (`.pb`) will also be in this directory.

```
ls $NEURON_PROFILE
```

Launch TensorBoard

In this step, we will process the Neuron profile data and launch TensorBoard.

5.1. Install the Neuron plugin for Tensorboard.

If you are using the DLAMI TensorFlow-Neuron Conda environment, please run the following to update TensorBoard before installing the Neuron plugin.

```
pip install "tensorboard<=2.4.0" --force-reinstall
```

Modify Pip repository configurations to point to the Neuron repository:

```
tee $VIRTUAL_ENV/pip.conf > /dev/null <<EOF
[global]
extra-index-url = https://pip.repos.neuron.amazonaws.com
EOF
```

```
pip install tensorboard-plugin-neuron
```

5.2. After collecting the raw profile data, we need to post-process it to create the log files used by the Neuron plugin. This can be done when launching TensorBoard by passing an extra flag `--run_neuron_profiler`. Using this flag will create the directory specified by `--logdir` and populate it with Neuron plugin data. Please note that the `NEURON_PROFILE` environment variable set in Step 4.1 must still point to the same directory as before.

```
tensorboard --logdir results --run_neuron_profiler
```

Note: If using TensorBoard >= 2.5, please use the `--load_fast=false` option when launching. `tensorboard --logdir results --run_neuron_profiler --load_fast=false`

5.3. After you see the following message, TensorBoard is ready to use. By default, TensorBoard will be launched at `localhost:6006` on the Deployment Instance.

```
...
Running neuron-profile
Serving TensorBoard on localhost; to expose to the network, use a proxy or pass --bind_
↪all
TensorBoard 2.4.1 at http://localhost:6006/ (Press CTRL+C to quit)
```

View results in TensorBoard

In this step, we will view the Neuron plugin for TensorBoard from a browser on your local development machine.

6.1. Connect to the Deployment Instance while enabling port forwarding. In this example, we assume TensorBoard has been launched using the default address `localhost:6006` on the Deployment Instance.

```
# if Ubuntu-based AMI
ssh -i <PEM key file> ubuntu@<instance DNS> -L 6006:localhost:6006

# if AL2-based AMI
ssh -i <PEM key file> ec2-user@<instance DNS> -L 6006:localhost:6006
```

6.2. In a browser, visit .

6.3. In the top navigation bar, switch from `Graphs` to `Neuron`. If it does not show up, please wait a while and refresh the page while the plugin loads. If the issue persists, check the `Inactive` dropdown list on the right and check for `Neuron`.

6.4. If TensorBoard failed to find the generated logs, you will see the following message:

In this case, please check the console output on the Deployment Instance where TensorBoard was launched for any warnings or error messages, and make sure the version of the `aws-neuron-tools` package is compatible.

Visualize graphs executed on Neuron

Show how the graph was partition to run on NeuronCores

To view how the graph was partitioned to run on NeuronCores, select "Device" under "Graph Color Schemes" in the left navigation bar.

Each operator will be colored according to the device used. In this example, light blue indicates an operator was executed on CPU, and orange indicates the operator was executed on NeuronCores. Operators that are white may have been optimized by the Neuron compiler and fused into another operation.

Inspect which operators consumes the most time

You can also view how long each operator took by changing to the "Compute time" color scheme.

This view will show time taken by each layer and will be colored according to how much relative time the layer took to compute. A lighter shade of red means that a relatively small portion of compute time was spent in this layer, while a darker red shows that more compute time was used.

Check out Neuron support operators for each framework

The "Compatibility" color scheme allows you to better understand what operators are currently supported by the Neuron compiler - green for compatible ops, red for incompatible ops, and yellow for subgraphs that contain both compatible and incompatible ops.

Filter view by device

Additionally, you can choose to filter by CPU and NeuronCores, which will only color ops that match the selected device(s).

Expand/collapse subgraphs and view operator details

Each rectangular node in the graph represents a subgraph that can be expanded or collapse by clicking on the name. Operators will be represented by ellipses, and can be clicked to reveal more information on that operator, such as inputs and execution device.

The `Expand All` and `Collapse All` buttons can be used to expand or collapse every subgraph. When using these features, the positioning of the graph may change when redrawing the new graph. Try using `Reset Position` button and zoom out by scrolling if the graph appears to be missing.

Viewing the Neuron profile data

On the right side of the Neuron plugin, information on the profiled inference will be displayed.

See performance summary

First is the "Neuron Performance Summary," which gives a quick overview on how Neuron executed the graph, including information on the number of NeuronCores and both on-NeuronCore time and on-CPU time.

Get a breakdown of time spent per NeuronCore

Next, the "Neuron Execution" will give more details on how a graph was partitioned for Neuron. Each entry in the table will show the order it was executed in, what type of device was used, the compute time (in microseconds), and the percentage of total time spent. To dive deeper into subgraphs, you can check the "Show Details" box to display the breakdown per NeuronCore.

Get a breakdown of time spent per operator

The "Op Time Table" section shows the cycle count per operator, much like the "Compute time" coloring for graph visualization. This table can be sorted by clicking the column names, and searched using the provided text box in the top right corner. Due to Neuron compiler optimizations, some of the compute may not be associated with any specific operator and will be categorized as `unknown`. Additionally, time spent moving data to and from NeuronCores will fall under `(ND_ENGINE_LOAD)`.

13.3 Helper Tools

This document is relevant for: `Inf1`

13.3.1 Neuron Check Model

Overview

Neuron Check Model tool provides user with basic information about the compiled and uncompiled model's operations without the use of TensorBoard-Neuron. For additional visibility into the models, please see *Neuron Plugin for TensorBoard (Inf1)*.

Neuron Check Model tool scans the user's uncompiled model and provides a table of the operations within the uncompiled model. By default, the table shows each operation type and number of instances of that type within model, and whether the type is supported in Neuron. If –show_names option is specified, the table shows each operation by name and whether the type of that operation is supported in Neuron.

If the model is already compiled, the tool also provides the table of operations as for uncompiled model. The table include the Neuron subgraph type and number of instances of that type, along with operations that have not been compiled to Neuron. Additionally, the tool displays a message showing the minimum number of NeuronCores required to run the model, followed by another table which shows the list of Neuron subgraphs by name and the number of pipelined NeuronCores used by each subgraph. More information about NeuronCore pipeline can be found in *NeuronCore Pipeline*. If –expand_subgraph option is specified, the operations within each subgraph are printed below the subgraph information.

Neuron Check Model tool is currently available for TensorFlow and MXNet. To check PT model, please use torch.neuron.analyze_model function as shown in PyTorch-Neuron Getting Started tutorial *ResNet50 model for Inferentia*

TensorFlow-Neuron Check Model

The following example shows how to run TensorFlow-Neuron Check Model tool with TensorFlow ResNet50 tutorial.

1. Start with the TensorFlow ResNet50 tutorial at *Running ResNet50 on Inferentia* and do the first three steps of the tutorial. Please stay in the Python environment that you setup during the tutorial.

2. Install needed tensorflow_hub package and download the tool:

```
pip install tensorflow_hub
wget https://raw.githubusercontent.com/aws/aws-neuron-sdk/master/src/neuron-gatherinfo/
↪tf_neuron_check_model.py
python tf_neuron_check_model.py -h
```

```
usage: tf_neuron_check_model.py [-h] [--show_names] [--expand_subgraph]
                                model_path

positional arguments:
  model_path         a TensorFlow SavedModel directory (currently supporting
                     TensorFlow v1 SaveModel only).

optional arguments:
  -h, --help         show this help message and exit
  --show_names       list operation by name instead of summarizing by type
                     (caution: this option will generate many lines of output
                     for a large model).
  --expand_subgraph  show subgraph operations.
```

3. After step 3 of the TensorFlow ResNet50 tutorial, you can check the uncompiled model to see Neuron supported operations (currently supporting TensorFlow v1 SaveModel only):

```
$ python tf_neuron_check_model.py ws_resnet50/resnet50/

* The following table shows the supported and unsupported operations within this␣
↪uncompiled model.
* Each line shows an operation type, the number of instances of that type within model,
* and whether the type is supported in Neuron.
* Some operation types are excluded from table because they are no-operations or␣
↪training-related operations:
 ['Placeholder', 'PlaceholderWithDefault', 'NoOp', 'Const', 'Identity', 'IdentityN',
↪'VarHandleOp',
 'VarIsInitializedOp', 'AssignVariableOp', 'ReadVariableOp', 'StringJoin',
↪'ShardedFilename', 'SaveV2',
 'MergeV2Checkpoints', 'RestoreV2']

Op Type           Num Instances   Neuron Supported ?
-------           -------------   ------------------
Pad               2               Yes
RandomUniform     54              Yes
Sub               54              Yes
Mul               54              Yes
Add               54              Yes
Conv2D            53              Yes
BiasAdd           54              Yes
FusedBatchNormV3  53              Yes
Relu              49              Yes
MaxPool           1               Yes
AddV2             16              Yes
Fill              56              Yes
Mean              1               Yes
MatMul            1               Yes
Softmax           1               Yes
Pack              1               Yes

* Total inference operations: 504
* Total Neuron supported inference operations: 504
* Percent of total inference operations supported by Neuron: 100.0
```

4. You can also check the compiled model to see the number of pipeline NeuronCores for each subgraph:

```
$ python tf_neuron_check_model.py ws_resnet50/resnet50_neuron/

* Found 1 Neuron subgraph(s) (NeuronOp(s)) in this compiled model.
* Use this tool on the original uncompiled model to see Neuron supported operations.
* The following table shows all operations, including Neuron subgraphs.
* Each line shows an operation type, the number of instances of that type within model,
* and whether the type is supported in Neuron.
* Some operation types are excluded from table because they are no-operations or␣
↪training-related operations:
 ['Placeholder', 'PlaceholderWithDefault', 'NoOp', 'Const', 'Identity', 'IdentityN',
↪'VarHandleOp',
 'VarIsInitializedOp', 'AssignVariableOp', 'ReadVariableOp', 'StringJoin',
↪'ShardedFilename', 'SaveV2',
 'MergeV2Checkpoints', 'RestoreV2']

Op Type   Num Instances   Neuron Supported ?
-------   -------------   ------------------
NeuronOp  1               Yes

* Please run this model on Inf1 instance with at least 1 NeuronCore(s).
* The following list show each Neuron subgraph with number of pipelined NeuronCores used␣
↪by subgraph
* (and subgraph operations if --expand_subgraph is used):

Subgraph Name                                                                  Num␣
↪Pipelined NeuronCores
-------------                                                                  -----------
↪--------------
conv5_block3_3_bn/FusedBatchNormV3/ReadVariableOp/neuron_op_d6f098c01c780733  1
```

5. When showing subgraph information, you can use –expand_subgraph to show operation types in each subgraph:

```
$ python tf_neuron_check_model.py ws_resnet50/resnet50_neuron/ --expand_subgraph

(output truncated to show subgraph information only)

Subgraph Name                                                                  Num␣
↪Pipelined NeuronCores
-------------                                                                  -----------
↪--------------
conv5_block3_3_bn/FusedBatchNormV3/ReadVariableOp/neuron_op_d6f098c01c780733  1

(continues on next page)

(continued from previous page)

```
    Softmax         1
```

6. Use –show_names to see full operation names (caution: this option will generate many lines of output for a large model):

```
$ python tf_neuron_check_model.py ws_resnet50/resnet50_neuron/ --show_names

* Found 1 Neuron subgraph(s) (NeuronOp(s)) in this compiled model.
* Use this tool on the original uncompiled model to see Neuron supported operations.
* The following table shows all operations, including Neuron subgraphs.
* Each line shows an operation name and whether the type of that operation is supported␣
↪in Neuron.
* Some operation types are excluded from table because they are no-operations or␣
↪training-related operations:
 ['Placeholder', 'PlaceholderWithDefault', 'NoOp', 'Const', 'Identity', 'IdentityN',
↪'VarHandleOp',
 'VarIsInitializedOp', 'AssignVariableOp', 'ReadVariableOp', 'StringJoin',
↪'ShardedFilename', 'SaveV2',
 'MergeV2Checkpoints', 'RestoreV2']

Op Name                                                                  Op Type   ␣
↪Neuron Supported ?
-------                                                                  -------    -
↪-----------------
conv5_block3_3_bn/FusedBatchNormV3/ReadVariableOp/neuron_op_d6f098c01c780733  NeuronOp ␣
↪Yes

* Please run this model on Inf1 instance with at least 1 NeuronCore(s).
* The following list show each Neuron subgraph with number of pipelined NeuronCores used␣
↪by subgraph
* (and subgraph operations if --expand_subgraph is used):

Subgraph Name                                                            Num␣
↪Pipelined NeuronCores
-------------                                                            -----------
↪---------------
conv5_block3_3_bn/FusedBatchNormV3/ReadVariableOp/neuron_op_d6f098c01c780733  1
```

MXNet-Neuron Check Model

The following example shows how to run MXNet-Neuron Check Model tool with MXNet ResNet50 tutorial.

1. Start with the MXNet ResNet50 tutorial at *Running Neuron Apache MXNet (Incubating) ResNet50 on Inferentia* and do the first three steps of the tutorial. Please stay in the Python environment that you setup during the tutorial.

2. Download the tool:

```
wget https://raw.githubusercontent.com/aws/aws-neuron-sdk/master/src/neuron-gatherinfo/
↪mx_neuron_check_model.py
python mx_neuron_check_model.py -h
```

```
usage: mx_neuron_check_model.py [-h] [--show_names] [--expand_subgraph]
                                model_path

positional arguments:
  model_path         path prefix to MXNet model (the part before -symbol.json)

optional arguments:
  -h, --help         show this help message and exit
  --show_names       list operation by name instead of summarizing by type
                     (caution: this option will generate many lines of output
                     for a large model).
  --expand_subgraph  show subgraph operations.
```

3. After step 3 of MXNet ResNet50 tutorial, you can check the uncompiled model to see Neuron supported operations:

```
$ python mx_neuron_check_model.py resnet-50

* The following table shows the supported and unsupported operations within this␣
↪uncompiled model.
* Each line shows an operation type, the number of instances of that type within model,
* and whether the type is supported in Neuron.
* Some operation types are excluded from table because they are no-operations or␣
↪training-related operations:
 ['null']

Op Type         Num Instances   Neuron Supported ?
-------         -------------   ------------------
BatchNorm       51              Yes
Convolution     53              Yes
Activation      50              Yes
Pooling         2               Yes
elemwise_add    16              Yes
Flatten         1               Yes
FullyConnected  1               Yes
SoftmaxOutput   1               No

* Total inference operations: 175
* Total Neuron supported inference operations: 174
* Percent of total inference operations supported by Neuron: 99.4
```

4. You can also check the compiled model to see the number of pipeline NeuronCores for each subgraph:

```
$ python mx_neuron_check_model.py resnet-50_compiled

* Found 1 Neuron subgraph(s) (_neuron_subgraph_op(s)) in this compiled model.
* Use this tool on the original uncompiled model to see Neuron supported operations.
* The following table shows all operations, including Neuron subgraphs.
* Each line shows an operation type, the number of instances of that type within model,
* and whether the type is supported in Neuron.
* Some operation types are excluded from table because they are no-operations or␣
↪training-related operations:
 ['null']
```

(continues on next page)

(continued from previous page)

```
Op Type               Num Instances   Neuron Supported ?
-------               -------------   ------------------
_neuron_subgraph_op   1               Yes
SoftmaxOutput         1               No

* Please run this model on Inf1 instance with at least 1 NeuronCore(s).
* The following list show each Neuron subgraph with number of pipelined NeuronCores used␣
↪by subgraph
* (and subgraph operations if --expand_subgraph is used):

Subgraph Name         Num Pipelined NeuronCores
-------------         -------------------------
_neuron_subgraph_op0  1
```

5. When showing subgraph information, you can use –expand_subgraph to show operation types in each subgraph:

```
$ python mx_neuron_check_model.py resnet-50_compiled --expand_subgraph

(output truncated to show subgraph information only)

Subgraph Name         Num Pipelined NeuronCores
-------------         -------------------------
_neuron_subgraph_op0  1
     Op Type         Num Instances
     -------         -------------
     BatchNorm       51
     Convolution     53
     Activation      50
     Pooling         2
     elemwise_add    16
     Flatten         1
     FullyConnected  1
```

6. Use –show_names to see full operation names (caution: this option will generate many lines of output for a large model):

```
$ python mx_neuron_check_model.py resnet-50_compiled --show_names

* Found 1 Neuron subgraph(s) (_neuron_subgraph_op(s)) in this compiled model.
* Use this tool on the original uncompiled model to see Neuron supported operations.
* The following table shows all operations, including Neuron subgraphs.
* Each line shows an operation name and whether the type of that operation is supported␣
↪in Neuron.
* Some operation types are excluded from table because they are no-operations or␣
↪training-related operations:
 ['null']

Op Name               Op Type              Neuron Supported ?
-------               -------              ------------------
_neuron_subgraph_op0  _neuron_subgraph_op  Yes
softmax               SoftmaxOutput        No
```

(continues on next page)

(continued from previous page)

```
* Please run this model on Inf1 instance with at least 1 NeuronCore(s).
* The following list show each Neuron subgraph with number of pipelined NeuronCores used␣
↪by subgraph
* (and subgraph operations if --expand_subgraph is used):

Subgraph Name         Num Pipelined NeuronCores
-------------         -------------------------
_neuron_subgraph_op0  1
```

13.3.2 Using Neuron GatherInfo Tool to collect debug and support information

Overview

The Neuron GatherInfo tool `neuron-gatherinfo.py` can assist in automating the collection and packaging of information from Neuron SDK tools that is useful to both user and AWS for issue resolution. The tool gathers log files and other system information. If being used to supply that info to AWS, the tool will redact proprietary and confidential information. The GatherInfo tool is supplied in source code form - available here: Neuron Gatherinfo

The tool enables developers to gather compiler and inference/runtime logs. Additionally, the common usage is from within one of the supported ML frameworks that have been integrated with Neuron, and information can be captured from those compile/runtime environments using the frameworks.

Steps Overview:

1. Obtain a copy of neuron-gatherinfo.py from Neuron Gatherinfo
2. Install into a location in your $PATH or into a location from where you can launch the script
3. Use with compile and/or runtime environments

Neuron-CC information gathering

Step 1: Re-run the compile steps for your workload with increased verbosity or debug levels

- For TensorFlow-Neuron, change the Python code as shown. Note that 'compiler-workdir' is expected to be an empty directory to prevent files from other runs from interfering with the information gathering. The call to the compile function has to be augmented with the **verbose** and the **compiler_workdir **arguments. In addition, please capture the stdout messages into a file (for example, by redirecting the stdout to a file)

```
tfn.saved_model.compile(model_dir, compiled_model_dir, compiler_args=['--verbose', '2',
↪'--pipeline', 'compile',  'SaveTemps'], compiler_workdir='./compiler-workdir')
```

- For Neuron Apache MXNet (Incubating), add compiler arguments as shown below and run the compilation process from an empty workdir:

```
import mxnet as mx
import os

from packaging import version
mxnet_version = version.parse(mx.__version__)
if mxnet_version >= version.parse("1.8"):
   import mx_neuron as neuron
else:
   from mxnet.contrib import neuron

...
os.environ['SUBGRAPH_INFO'] = '1'
compile_args = { '--verbose' : 2, '--pipeline' : 'compile', 'flags' : ['SaveTemps'] }
csym, cargs, cauxs = neuron.compile(sym, args, auxs, inputs=inputs, **compile_args)
```

Step 2: Run neuron-gatherinfo.py to gather information to share

The output result will be a tar.gz file.

Neuron Runtime information gathering

Step 1: EXECUTE inference steps for your workload with increased verbosity or debug levels

In the case of runtime information, the tool **neuron-dump.py** is used by **neuron-gatherinfo.py **to gather that information. Make sure that you have the neuron tools package (aws-neuron-tools) installed.

Step 2: Run neuron-gatherinfo.py to gather information to share

The output result will be a tar.gz file.

Tool Usage Reference

Run neuron-gatherinfo.py using the "—help" option:

```
bash $ ~/bin/neuron-gatherinfo.py --help
usage: neuron-gatherinfo.py [-h] [--additionalfileordir ADDFLDIR] [-c CCDIR]
                            [-i] [-f FILTERFILE] [-m] -o OUTDIR [-r RTDIR] -s
                            STDOUT [-v]

    Usage: /home/user/bin/neuron-gatherinfo.py [options]
    This program is used to gather information from this system for analysis
    and debugging

optional arguments:
  -h, --help            show this help message and exit
  --additionalfileordir ADDFLDIR
                        Additional file or directory that the user wants to
```

(continues on next page)

(continued from previous page)

```
                        provide in the archive. The user can sanitize this
                        file or directory before sharing
  -c CCDIR, --compileroutdir CCDIR
                        Location of the neuron-cc generated files
  -i, --include         By default, only the lines containing (grep) patterns
                        like 'nrtd|neuron|kernel:' from the syslog are copied.
                        Other lines are excluded. Using this option allows the
                        timestamp section of other lines to be included. The
                        rest of the contents of the line itself are elided.
                        Providing the timestamp section may provide time
                        continuity while viewing the copied syslog file
  -f FILTERFILE, --filter FILTERFILE
  -m, --modeldata       By using this option, the entire compiler work
                        directory's contents will be included (excluding the
                        .pb files, unless an additional option is used). This
                        would include model information, etc. The files that
                        are included, by default, are these: graph_def.neuron-
                        cc.log, all_metrics.csv, hh-tr-operand-
                        tensortensor.json
  -o OUTDIR, --out OUTDIR
                        The output directory where all the files and other
                        information will be stored. The output will be stored
                        as an archive as well as the actual directory where
                        all the contents are copied. This will allow a simple
                        audit of the files, if necessary. *** N O T E ***:
                        Make sure that this directory has enough space to hold
                        the files and resulting archive
  -r RTDIR, --runtimeoutdir RTDIR
                        Location of the neuron runtime generated files
  -s STDOUT, --stdout STDOUT
                        The file where the stdout of the compiler run was
                        saved
  -v, --verbose         Verbose mode displays commands executed and any
                        additional information which may be useful in
                        debugging the tool itself
```

Examples

Example 1: no ML model information gathered (default behavior)

In this case, the tool will archive just the default information gathering:

```
bash $ sudo ~/bin/neuron-gatherinfo.py   -o compile-and-run-info-for-debugging-no-model-
↪info  -i --verbose  -s stdout-from-compile_resnet50.out -c compiler-workdir

Running cmd: lscpu and capturing output in file: /home/user/tutorials-3/compile-and-run-
↪info-for-debugging-no-model-info/neuron-gatherinfo/report-lscpu.txt
Running cmd: lshw and capturing output in file: /home/user/tutorials-3/compile-and-run-
↪info-for-debugging-no-model-info/neuron-gatherinfo/report-lshw.txt
Running cmd: lspci | grep -i Amazon and capturing output in file: /home/user/tutorials-3/
↪compile-and-run-info-for-debugging-no-model-info/neuron-gatherinfo/report-lspci.txt
```

(continues on next page)

(continued from previous page)

```
Running cmd: neuron-cc --version and capturing output in file: /home/user/tutorials-3/
↪compile-and-run-info-for-debugging-no-model-info/neuron-gatherinfo/report-neuron-cc.txt
Running cmd: neuron-ls and capturing output in file: /home/user/tutorials-3/compile-and-
↪run-info-for-debugging-no-model-info/neuron-gatherinfo/report-neuron-ls.txt
<SNIP>
    ******
    Archive created at:
        /home/user/tutorials-3/compile-and-run-info-for-debugging-no-model-info/neuron-

13.4 NeuronPerf (Beta)

NeuronPerf is a lightweight Python library with a simple API that enables fast measurements of performance when running models using Neuron.

13.4.1 NeuronPerf Quickstart

To install NeuronPerf in your Neuron environment, execute:

```
$ pip install neuronperf --extra-index-url=https://pip.repos.neuron.amazonaws.com
```

Refer to the *NeuronPerf Examples* and *NeuronPerf User Guide* to get started.

13.4.2 NeuronPerf User Guide

This document is relevant for: `Inf1`

NeuronPerf Overview

NeuronPerf is a lightweight Python library that can help you easily benchmark your models with Neuron hardware.

NeuronPerf supports Neuron releases for PyTorch, Tensorflow, and MXNet. It is used internally by the Neuron team to generate performance benchmarking numbers.

When interacting with NeuronPerf, you will typically import the base package along with one of the submodule wrappers, for example:

```
import neuronperf
import neuronperf.torch
```

You may then benchmark and/or compile one or more models with NeuronPerf. For example,

```
reports = neuronperf.torch.benchmark(model, inputs, ...)
```

The `compile` and `benchmark` methods must be accessed through one of the supported framework submodules.

Benchmarking

All NeuronPerf `benchmark` calls require a minimum of two arguments:

1. A filename
2. Inputs

The filename may refer to:

1. A Neuron-compiled model (e.g. `my_model.pt`)
2. A *Model Index*.

A Model Index is useful for benchmarking more than one model in a single session.

Compiling

NeuronPerf also provides a standard interface to all Neuron frameworks through the `compile` API.

```
model_index = neuronperf.torch.compile(model, inputs, ...)
```

This is completely optional. You may use the standard compilation guides for supported frameworks.

Next Steps

Take a look at the simple *NeuronPerf Examples*, *NeuronPerf Benchmark Guide*, *NeuronPerf Compile Guide*, and *NeuronPerf API*.

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

NeuronPerf Terminology

- Model Inputs - An individual input or `list` of inputs - Example: `inputs = [(torch.ones((batch_size, 5))) for batch_size in batch_sizes]` - Each input is associated with the `batch_sizes` specified, in the same order - Each input is fed individually to a corresponding model - If an input is provided as a `tuple`, it will be destructured to `model(*input)` to support multiple args - See *NeuronPerf Framework Notes* for framework-specific requirements
- **Latency**
  - Time to execute a single `model(input)`
  - Typically measured in milliseconds
- **Model**
  - Your data model; varies by framework. See *NeuronPerf Framework Notes*
  - Models may be wrapped by submodules (`torch`, `tensorflow`, `mxnet`) as callables
- **Model Index**
  - A JSON file that tracks compiled model artifacts
- **Model Inputs**
  - A `tuple` of inputs passed to a model, i.e. a single complete example

  - Example: `input = (torch.ones((5, 3, 224, 224)),)`

- **Throughput**
  - Inferences / second

This document is relevant for: `Inf1`

NeuronPerf Examples

This page walks through several examples of using NeuronPerf, starting with the simplest way—using a compiled model. We will also see how we can use NeuronPerf to perform a hyperparameter search, and manage the artifacts produced, as well as our results.

Benchmark a Compiled Model

This example assumes you have already compiled your model for Neuron and saved it to disk. You will need to adapt the batch size, input shape, and filename for your model.

```
import torch  # or tensorflow, mxnet

import neuronperf as npf
import neuronperf.torch  # or tensorflow, mxnet

# Construct dummy inputs
batch_sizes = 1
input_shape = (batch_sizes, 3, 224, 224)
inputs = torch.ones(input_shape)  # or numpy array for TF, MX

# Benchmark and save results
reports = npf.torch.benchmark("your_model_file.pt", inputs, batch_sizes)
npf.print_reports(reports)
npf.write_csv(reports)  # save table of most useful data, or...
npf.write_json(reports)  # save everything
```

```
INFO:neuronperf.benchmarking - Benchmarking 'your_model_file.pt', ~8.0 minutes remaining.
throughput_avg    latency_ms_p50    latency_ms_p99    n_models          pipeline_size   ␣
↪ workers_per_model batch_size        model_filename
296766.5          0.003             0.003             1                 1               ␣
↪ 1                 1                 your_model_file.pt
3616109.75        0.005             0.008             24                1               ␣
↪ 1                 1                 your_model_file.pt
56801.0           0.035             0.04              1                 1               ␣
↪ 2                 1                 your_model_file.pt
3094419.4         0.005             0.051             24                1               ␣
↪ 2                 1                 your_model_file.pt
```

Let's suppose you only wish to test two specific configurations. You wish to benchmark 1 model and 1 worker thread, and also with 2 worker threads for 15 seconds each. The call to `benchmark` becomes:

```
reports = npf.torch.benchmark(filename, inputs, batch_sizes, n_models=1, workers_per_
↪model=[1, 2], duration=15)
```

You can also add a custom model name to reports.

```
reports = npf.torch.benchmark(..., model_name="MyFancyModel")
```

See the *NeuronPerf Benchmark Guide* for further details.

Benchmark a Model from Source

In this example, we define, compile, and benchmark a simple (dummy) model using PyTorch.

We'll assume you already have a PyTorch model compiled for Neuron with the filename `model_neuron_b1.pt`. Furthermore, let's assume the model was traced with a batch size of 1, and has an input shape of (3, 224, 224).

Listing 1: `test_simple_pt.py`

```
import torch
import torch.neuron

import neuronperf as npf
import neuronperf.torch

# Define a simple model
class Model(torch.nn.Module):
    def forward(self, x):
        x = x * 3
        return x + 1

# Instantiate
model = Model()
model.eval()

# Define some inputs
batch_sizes = [1]
inputs = [torch.ones((batch_size, 3, 224, 224)) for batch_size in batch_sizes]

# Compile for Neuron
model_neuron = torch.neuron.trace(model, inputs)
model_neuron.save("model_neuron_b1.pt")

# Benchmark
reports = npf.torch.benchmark("model_neuron_b1.pt", inputs, batch_sizes)

# View and save results
npf.print_reports(reports)
npf.write_csv(reports, "model_neuron_b1.csv")
```

```
(aws_neuron_pytorch_p36) ubuntu@ip-172-31-11-122:~/tmp$ python test_simple_pt.py

Compile and Benchmark a Model

Here is an end-to-end example of compiling and benchmarking a ResNet-50 model from `torchvision`.

Listing 2: `test_resnet50_pt.py`

```
import torch
import torch_neuron

import neuronperf as npf
import neuronperf.torch

from torchvision import models

# Load a pretrained ResNet50 model
model = models.resnet50(pretrained=True)

# Select a few batch sizes to test
filename = 'resnet50.json'
batch_sizes = [5, 6, 7]

# Construct example inputs
inputs = [torch.zeros([batch_size, 3, 224, 224], dtype=torch.float32) for batch_size in␣
↪batch_sizes]

# Compile
npf.torch.compile(
```

(continues on next page)

(continued from previous page)

```
        model,
        inputs,
        batch_sizes=batch_sizes,
        filename=filename,
)

# Benchmark
reports = npf.torch.benchmark(filename, inputs)

# View and save results
npf.print_reports(reports)
npf.write_csv(reports, 'resnet50_results.csv')
npf.write_json(reports, 'resnet50_results.json')
```

Benchmark on CPU or GPU

When benchmarking on CPU or GPU, the API is slightly different. With CPU or GPU, there is no compiled model to benchmark, so instead we need to directly pass a reference to the model class that will be instantiated.

Note: GPU benchmarking is currently only available for PyTorch.

CPU:

```
cpu_reports = npf.cpu.benchmark(YourModelClass, ...)
```

GPU:

```
gpu_reports = npf.torch.benchmark(YourModelClass, ..., device_type="gpu")
```

Please refer to *Benchmark on CPU or GPU* for details and an example of providing your model class.

NeuronPerf Benchmark Guide

The call to `neuronperf[torch/tensorflow/mxnet/cpu].benchmark` is used to measure your model performance. It will choose reasonable defaults if none are provided, and will return back reports that summarize the benchmarking results.

What is the default behavior of `benchmark`?

That will depend how you provided your model and how your model was compiled.

The two most common ways to provide your model are:

1. Provide the path to your compiled model
2. Provide the path to a model index from `neuronperf.compile` (a JSON file)

Data Parallel

If you choose 1, then…

Your model is benchmarked on provided `inputs` in 4 different configurations:

1. A single model on 1 NeuronCore with one worker (min. latency)
2. A single model on 1 NeuronCore with two workers (max. throughput / NC)
3. `MAX` models on `MAX` NeuronCores with one worker (min. latency + max. instance usage)
4. `MAX` models on `MAX` NeuronCores with two workers (max. throughput + max. instance usage)

The value `MAX` is automatically determined by your instance size. If it can't be identified, those configurations will be skipped.

The primary benefit of (3) and (4) is to verify that your model scales well at maximum instance usage.

If you chose 2, then…

- Your input parameters to `benchmark` (`batch_sizes`, etc.) are treated as filters on the index
- Each remaining model configuration is benchmarked as described in (1)

Pipeline

Pipeline mode is active when using a Neuron device and `pipeline_sizes > 1`. The same behavior as described in Data Parallel applies, except that only one worker configuration is executed: the optimal number of workers for your pipeline size, unless manually overridden.

Parameters

Below are some useful and common parameters to tweak. Please see the *NeuronPerf API* for full details.

- `n_models` controls how many models to load. The default behavior is `n_models=[1, MAX]`.
- `workers_per_model` controls how many worker threads will be feeding inputs to each model. The default is automatically determined.
- `pipeline_sizes` tells the benchmarker how many cores are needed for your model so that each model instance can be loaded properly. Default is 1.
- `duration` controls how long to run each configuration.
- `batch_sizes` is used to inform the benchmarker of your input shape so that throughput can be computed correctly.

Almost all NeuronPerf behaviors are controllable via arguments found in the *NeuronPerf API*. This guide attempts to provide some context and examples for those arguments.

Inputs

Models accept one or more inputs to operate on. Since NeuronPerf needs to support multiple inputs for multiple models, as well as multi-input models, there are some details that may need your attention. See the *NeuronPerf Framework Notes* for details.

Multi-input Models

If your model accepts multiple inputs, you must provide them in a `tuple`. For example, suppose you have a model like this:

```
class Model(torch.nn.Module):
        def forward(self, x, y, z):
                ...
                return output
```

In order for NeuronPerf to pass along your multiple inputs correctly, you should provide them as a `tuple`:

```
inputs = (x, y, z)
npf.torch.benchmark(model_filename, inputs, ...)
```

If you are compiling and/or benchmarking multiple models, you can pass different sized inputs as a list of tuples:

```
inputs = [(x1, y1, z1), (x2, y2, z2), ...]
npf.torch.benchmark(model_filename, inputs, ...)
```

Preprocessing and Postprocessing

Many models have additional preprocessing and postprocessing steps involved that may add non-negligible overhead to inference time. NeuronPerf supports these use cases through the use of custom functions.

Preprocessing

Recall that NeuronPerf expects (or wraps) each model input into a `tuple`. These tuples will be unpacked before calling your model.

Here is an example for a model with one input. The example multiples the input by 5 before inference.

```
def preprocess_fn(x):
    return x * 5

...

# Benchmark with custom preprocessing function
reports = npf.torch.benchmark(
        filename,
        inputs,
        ...,
        preprocess_fn = preprocess_fn,
)
```

Or if your model expects multiple inputs:

```
def preprocess_fn(x, y, z):
    return x / 255, y / 255, z / 255

...

# Benchmark with custom preprocessing function
reports = npf.torch.benchmark(
        filename,
        inputs,
        ...,
        preprocess_fn = preprocess_fn,
)
```

Postprocessing

Postprocessing is almost identical to preprocessing, except that your function will receive whatever the output of your model is, exactly as returned without modification. There are no type guarantees.

```
def postprocess_fn(x):
   return x.argmax()

...

# Benchmark with custom preprocessing function
reports = npf.torch.benchmark(
      filename,
      inputs,
      ...,
      postprocess_fn = postprocess_fn,
)
```

Minimal Latency

Suppose you are interested in the minimal latency achievable with your model. In this case, there is no need for more than one worker to execute at a time. We can manually specify the number of workers to use. See below *Worker Threads*.

Worker Threads

The argument `workers_per_model` controls the number of worker threads that are trying to prepare and load examples onto a single NeuronCore at a time. Therefore, a value of 1 corresponds to 1 thread / model. If `n_models=16`, then there would be 16 worker threads, one per model. This number is selected based upon whether you are using DataParallel (i.e. `pipeline_sizes == 1`), or Pipeline Mode (`pipeline_sizes != 1`).

By default, NeuronPerf will try to pick try multiple combinations of model copies and workers. You may be interested in controlling this manually.

```
reports = npf.torch.benchmark('model_neuron_b1.pt', ..., workers_per_model=1)
```

You may also pass a list, as with other parameters:

```
workers_per_model = [1, 2] # Same as the default for data parallel
reports = npf.torch.benchmark('model_neuron_b1.pt', ..., workers_per_
↪model)
```

With the default number of *Model Copies*, a call to `print_results` might look like this:

```
throughput_avg latency_ms_p50 latency_ms_p99 n_models       pipeline_size  workers_per_
↪model batch_size     model_filename
307.25         3.251          3.277          1              1              1            ␣
↪    1              models/a5cff386-89ca-4bbf-9087-d0e624c3c604.pt
2746.0         5.641          6.82           16             1              1            ␣
↪    1              models/a5cff386-89ca-4bbf-9087-d0e624c3c604.pt
329.5          6.053          6.108          1              1              2            ␣
↪    1              models/a5cff386-89ca-4bbf-9087-d0e624c3c604.pt
2809.0         10.246         12.52          16             1              2            ␣
↪    1              models/a5cff386-89ca-4bbf-9087-d0e624c3c604.pt
```

Model Copies

By default, NeuronPerf will benchmark two settings for `n_models`:

1. A single copy
2. The maximum number number of copies for your instance size

You can override this behavior by passing `n_models` to `benchmark`, as shown below:

```
reports = npf.torch.benchmark('model_neuron_b1.pt', ..., n_models=6)
```

or

```
n_models = list(range(1, 10))
reports = npf.torch.benchmark('model_neuron_b1.pt', ..., n_models=n_models)
```

Pipeline Mode

By default, NeuronPerf will assume you intend to use DataParallel, with two exceptions:

- You compiled your model using NeuronPerf for pipeline mode
- You constructed a neuronperf_model_index that uses pipeline mode

You can also manually tell NeuronPerf that your model was compiled for pipeline mode. It is similar to how other arguments are passed.

```
reports = npf.torch.benchmark('model_neuron_b1.pt', ..., pipeline_sizes=2)
```

If you are passing multiple models in an index, then you should pass a list for `pipeline_sizes`.

```
reports = npf.torch.benchmark('model_index.json', ..., pipeline_sizes=[1, 2, 3])
```

Duration

NeuronPerf will benchmark each configuration specified for 60 seconds by default. You can control the duration by passing `duration` (in seconds).

```
reports = npf.torch.benchmark('model_index.json', ..., duration=10)
```

> **Warning:** If you make the duration too short, it may expire before all models are loaded and have had time to execute.

Custom Datasets (Beta)

Currently, only PyTorch supports custom datasets, and the interface is subject to change. If you provide a custom dataset, it will be fully executed on each loaded model copy. So if you provide `n_models=2`, your dataset will be run through twice in parallel.

To use this API, call `benchmark` passing a `torch.utils.data.Dataset` to `inputs`. You can easily create your own `Dataset` by implementing the interface, or use one of the available datasets. For example:

```
import torchvision

dataset = torchvision.datasets.FashionMNIST(
   root="data",
   train=False,
   download=True,
   transform=ToTensor()
)

reports = npf.torch.benchmark('model_index.json', inputs=dataset, batch_sizes=[8],␣
↪preprocess_fn=lambda x: x[0], loop_dataset=False)
```

Note: The `preprocess_fn` is required here to extract image input from the `(image, label)` tuple generated by dataloader. If the length of dataset is not sufficient to get the runtime performance, one can set `loop_dataset=True` to rerun dataset until certain duration.

Results

Viewing and Saving

There are currently three ways to view results.

- **`neuronperf.print_reports(...)`**
  - Dump abbrieviated results in your terminal
- **`neuronperf.write_csv(...)`**
  - Store metrics of interest as CSV
- **`neuronperf.write_json(...)`**

- Store everything as JSON

See the *NeuronPerf API* for full details.

Full Timing Results

NeuronPerf automatically combines and summarizes the detailed timing information collecting during benchmarking. If you wish to receive everything back yourself, you can use:

```
results = npf.torch.benchmark('model_index.json', ..., return_timers=True)
```

If you later wish to produce reports the same way that NeuronPerf does internally, you can call:

```
reports = npf.get_reports(results)
```

Verbosity

Verbosity is an integer, currently one of `{0, 1, 2}`, where:

- 0 = SILENT
- 1 = INFO (default)
- 2 = VERBOSE / DEBUG

Example:

```
reports = npf.torch.benchmark(..., n_models=1, duration=5, verbosity=2)
```

```

↪     1              models/model_b1_p1_83bh3hhs.pt
```

Internal Process Model

For each model loaded (see *Model Copies*), a process is spawned. Each process may use multiple threads (see *Worker Threads*). The threads will continue to load examples and keep the hardware busy.

NeuronPerf spawns processes slightly differently between frameworks. For PyTorch and Apache MXNet (Incubating), processes are forked. For Tensorflow/Keras, a fresh interpreter is launched, and benchmarkers are serialized and run as a script.

If you suspect you are having trouble due to the way processes are managed, you have two mechanisms of control:

```
reports = npf.torch.benchmark(..., multiprocess=False)
```

Default is `True`, and `False` will disable multiprocessing and run everything inside a single parent process. This may not work for all frameworks beyond the first model configuration, because process teardown is used to safely deallocate models from the hardware. It is not recommeneded to benchmark this way.

```
reports = npf.torch.benchmark(..., multiinterpreter=True)
```

This flag controls whether a fresh interpreter is used instead of forking. Defaults to `False` except with Tensorflow/Keras.

Benchmark on CPU or GPU

When benchmarking on CPU or GPU, the API is slightly different. With CPU or GPU, there is no compiled model to benchmark, so instead we need to directly pass a reference to the model class that will be instantiated.

Note: GPU benchmarking is currently only available for PyTorch.

CPU:

```
cpu_reports = npf.cpu.benchmark(YourModelClass, ...)
```

GPU:

```
gpu_reports = npf.torch.benchmark(YourModelClass, ..., device_type="gpu")
```

Your model class will be instantiated in a subprocess, so there are some things to keep in mind.

- **Your model class must be defined at the top level inside a Python module**
  - i.e. don't place your model class definition inside a function or other nested scope
- If your model class has special Python module dependencies, consider importing them inside your class `__init__`
- If your model class expects constructor arguments, wrap your class so that it has no constructor arguments

Example of a wrapped model class for CPU/GPU benchmarking:

```
class ModelWrapper(torch.nn.Module):
   def __init__(self):
      super().__init__()
      from transformers import AutoModelForSequenceClassification
      model_name = "bert-base-cased"
```

(continues on next page)

(continued from previous page)

```
        self.bert = AutoModelForSequenceClassification.from_pretrained(model_name, return_
↪dict=False)
        self.add_module(model_name, self.bert)

    def forward(self, *inputs):
        return self.bert(*inputs)

reports = npf.torch.benchmark(ModelWrapper, inputs, device_type="gpu")
```

This document is relevant for: `Inf1`

NeuronPerf Evaluate Guide

NeuronPerf has a new API for evaluating model accuracy on Neuron hardware. This API is currently only available for PyTorch.

You can access the API through standard `benchmark()` by passing an additional kwarg, `eval_metrics`.

For example:

```
reports = npf.torch.benchmark(
    model_index_or_path,
    dataset,
    n_models=1,
    workers_per_model=2,
    duration=0,
    eval_metrics=['accuracy', 'precision']
)
```

In this example, we fix `n_models` and `n_workers` because replicating the same model will not impact accuracy. We also set `duration=0` to allow benchmarking to run untimed through all dataset examples.

Because this call can be tedious to type, a convenience function is provided:

```
reports = npf.torch.evaluate(model_index_or_path, dataset, metrics=['accuracy',
↪'precision'])
```

The `dataset` can be any iterable object that produces `tuple(*INPUTS, TARGET)`.

If `TARGET` does not appear in the last column for your dataset, you can customize this by passing `eval_target_col`.

For example:

```
reports = npf.torch.evaluate(model_index_or_path, dataset, metrics='accuracy', eval_
↪target_col=1)
```

You can list the currently available metrics.

```
>>> npf.list_metrics()                                                          ␣
↪              |.....
Name                      Description                                           ␣
↪              |.....
```

(continues on next page)

```

New metrics may appear in the list after importing a submodule. For example, `import neuronperf.torch` will register a new `topk` metric.

Custom Metrics

Simple Variants

If you wish to register a metric that is a slight tweak of an existing metric with different `init` args, you can use `register_metric_from_existing()`:

```
npf.register_metric_from_existing("topk", "topk_3", k=3)
```

This example registers a new metric `topk_3` from existing metric `topk`, passing `k=3` as at `init` time.

New Metrics

You can register your own metrics using `register_metric()`.

You metrics must extend `BaseEvalMetric`:

```
class BaseEvalMetric(ABC):
    """
    Abstract base class BaseEvalMetric from which other metrics inherit.
    """

    @abstractmethod
    def process_record(self, output: Any = None, target: Any = None) -> None:
        """Process an individual record and return the result."""
        pass

    @staticmethod
    def aggregate(metrics: Iterable["BaseEvalMetric"]) -> Any:
        """Combine a sequence of metrics into a single result."""
        raise NotImplementedError
```

For example:

```
import neuronperf as npf

class MyCustomMetric(npf.BaseEvalMetric):
    def __init__(self):
        super().__init__()
        self.passing = 0
        self.processed = 0

    def process_record(self, outputs, target):
        self.processed += 1
        if outputs == target:
            self.passing += 1

    @staticmethod
    def aggregate(metrics):
        passing = 0
        processed = 0
        for metric in metrics:
            passing += metric.passing
```

(continues on next page)

(continued from previous page)

```
            processed += metric.processed
        return passing / processed if processed else 0

npf.register_metric("MyCustomMetric", MyCustomMetric)
```

This document is relevant for: Inf1

NeuronPerf Compile Guide

If you wish to compile multiple configurations at once, NeuronPerf provides a simplified and uniform API across frameworks. The output is a neuronperf_model_index that tracks the artifacts produces, and can be passed directly to the *benchmark* routine for a streamlined end-to-end process. This may be useful if you wish to test multiple configurations of your model on Neuron hardware.

You can manually specify the model index filename by passing `filename`, or let NeuronPerf generate one and return it for you. Compiled artifacts will be placed in a local `models` directory.

Please note that the default behavior will be to compile your model for each pipeline size, batch size, and cast mode in combination, which may take some time.

```
# Select a few batch sizes and pipeline configurations to test
batch_sizes = [1, 5, 10]
pipeline_sizes = [1, 2, 4]

# Construct example inputs
example_inputs = [torch.zeros([batch_size, 3, 224, 224], dtype=torch.float16) for batch_
↪size in batch_sizes]

# Compile all configurations
index = neuronperf.torch.compile(
   model,
   example_inputs,
   batch_sizes=batch_sizes,
   pipeline_sizes=pipeline_sizes,
)
```

If you wished to benchmark specific subsets of configurations, you could compile the specific configurations independently and later combine the results into a single index, as shown below.

```
# Compile with pipeline size 1 and vary batch dimension
batch_index = neuronperf.torch.compile(
   model,
   example_inputs,
   batch_sizes=batch_sizes,
   pipeline_sizes=1,
)

# Compile with batch size 1 and vary pipeline dimension
pipeline_index = neuronperf.torch.compile(
   model,
```

(continues on next page)

(continued from previous page)

```
    example_inputs[0],
    batch_sizes=1,
    pipeline_sizes=pipeline_sizes,
)

index = neuronperf.model_index.append(batch_index, pipeline_index)
neuronperf.model_index.save(index, 'model_index.json')
```

The `compile` function supports `batch_sizes`, `pipeline_sizes`, `cast_modes`, and custom `compiler_args`. If there is an error during compilation for a requested configuration, it will be logged and compilation will continue onward without terminating. (This is to support long-running compile jobs with many configurations.)

NeuronPerf Model Index Guide

A **model index** is a JSON file that tracks information about one or more compiled models. You can generate them using `compile`, by using the API described here, or you may create them manually in a text editor.

After a call to `compile` you may notice that you now have a `models` directory. You will also spot a new file named something like `model_83b3raj2.json` in your local directory, if you didn't provide a `filename` yourself.

A model index is not intended to be opaque; you should feel free to open, inspect, and modify it yourself. It contains some information about the artifacts that were compiled. Individual models referenced by the index can be handed to `benchmark` directly along with an example input, or you may pass the entire index as in the basic example above. Here is an example index:

```
python3 -m json.tool model_index.json
```

```
{
    "version": "0.0.0.0+0bc220a",
    "model_configs": [
        {
            "filename": "models/model_b1_p1_38793jda.pt",
            "input_idx": 0,
            "batch_size": 1,
            "pipeline_size": 1,
            "compile_s": 5.32
        }
    ]
}
```

An index is useful for keeping track of your compiled artifacts and their parameters. The advantages of using `neuronperf.[torch/tensorflow/mxnet].compile` are clearer when we wish to compile multiple variants of our model and benchmark all of them at the same time. All of the model artifacts and the index can be destroyed using `model_index.delete('model_index.json')`.

Benchmarking

When benchmarking with an index, there are some important details to keep in mind. If you originally built the index using a set of inputs, the model index has associated the `inputs` with the compiled models by their positional index.

For example:

```
batch_sizes = [1, 2]
inputs = [torch.zeros((b, 100)) for b in batch_sizes]
```

Here, `inputs[0]` corresponds to batch size 1. Therefore, the model index will contain a reference to input 0 for that model. When you call `benchmark`, you must pass inputs with the same shape in the same positions as at compile time.

Note: It's only necessary that there is an input with the correct shape at``inputs[input_index]``. The example data itself is not important.

Working with Indexes

The API detail below describes utilities for working with indexes. An `index` can be either a loaded index (JSON) or the path to an index (it will be loaded automatically).

Creating

```
index = neuronperf.model_index.create('/path/to/model', batch_size=1)
filename = neuronperf.model_index.save(index)
```

Once you have an index, you can pass its path directly to `benchmark`. You can also pass a custom filename instead:

```
index = neuronperf.model_index.create('/path/to/model', batch_size=1)
neuronperf.model_index.save(index, 'my_index.json')
```

Appending

If **multiple models use the same inputs**, you can append them together. For example, if you have the same batch size with multiple pipeline sizes, the inputs are the same, but the model changes.

```
pipeline_sizes = [1, 2, 3, 4]
indexes = [neuronperf.model_index.create(f'/path/to/model_p{p}', pipeline_size=p, batch_
↪size=5) for p in pipeline_sizes]
index = neuronperf.model_index.append(*indexes)
neuronperf.model_index.save(index, 'my_index.json')
```

Filtering

You can construct a new model index that is filtered by some parameter. For example, to get a new index with only batch sizes [1, 2], you could do:

```
new_index = neuronperf.model_index.filter(index, batch_sizes=[1, 2])
```

You can also benchmark subset of a model index by passing only the subset parameters of interest, but remember to ensure you provide the correct number of inputs for the index (even if some are not used).

For example, if you an index with models at `batch_sizes = [1, 2, 3]`, but only wish to benchmark batch size 2:

```
batch_sizes = [1, 2, 3]
inputs = [torch.zeros((b, 100)) for b in batch_sizes]
reports = neuronperf.torch.benchmark('model_index.json', inputs, batch_sizes=2)
```

Copying

You can copy an index to a new location with `neuronperf.model_index.copy(index, new_index_name, new_index_dir)`. This is mostly useful in combination with `filter`/`append`.

Deleting

If you wish to keep your compiled models, just delete the model index file yourself. If you want to delete your model index and all associated artifacts, use:

```
neuronperf.model_index.delete('my_index.json')
```

13.4.3 NeuronPerf API Reference

This document is relevant for: `Inf1`

NeuronPerf API

Due to a bug in Sphinx, some of the type annotations may be incomplete. You can `download the source code here`. In the future, the source will be hosted in a more browsable way.

compile(*compile_fn*, *model*, *inputs*, *batch_sizes: Union[int, List[int]] = None*, *pipeline_sizes: Union[int, List[int]] = None*, *performance_levels: Union[str, List[int]] = None*, *models_dir: str = 'models'*, *filename: str = None*, *compiler_args: dict = None*, *verbosity: int = 1*, **args*, ***kwargs*) → str:

Compiles the provided model with each provided example input, pipeline size, and performance level. Any additional compiler_args passed will be forwarded to the compiler on every invocation.

Parameters

- **model** – The model to compile.
- **inputs** (*list*) – A list of example inputs.
- **batch_sizes** – A list of batch sizes that correspond to the example inputs.
- **pipeline_sizes** – A list of pipeline sizes to use. See *NeuronCore Pipeline*.

- **performance_levels** – A list of performance levels to try. Options are: 0 (max accuracy), 1, 2, 3 (max performance, default). See *Mixed precision and performance-accuracy tuning (neuron-cc)*.
- **models_dir** (*str*) – The directory where compilation artifacts will be stored.
- **model_name** (*str*) – An optional model name tag to apply to compiled artifacts.
- **filename** (*str*) – The name of the model index to write out. If not provided, a name will be generated and returned.
- **compiler_args** (*dict*) – Additional compiler arguments to be forwarded with every compilation.
- **verbosity** (*int*) – 0 = error, 1 = info, 2 = debug

Returns A model index filename. If a configuration fails to compile, it will not be included in the index and an error will be logged.

Return type str

benchmark(*load_fn: Callable[[str, int], Any], model_filename: str, inputs: Any, batch_sizes: Union[int, List[int]] = None, duration: float = BENCHMARK_SECS, n_models: Union[int, List[int]] = None, pipeline_sizes: Union[int, List[int]] = None, cast_modes: Union[str, List[str]] = None, workers_per_model: Union[int, None] = None, env_setup_fn: Callable[[int, Dict], None] = None, setup_fn: Callable[[int, Dict, Any], None] = None, preprocess_fn: Callable[[Any], Any] = None, postprocess_fn: Callable[[Any], Any] = None, dataset_loader_fn: Callable[[Any, int], Any] = None, verbosity: int = 1, multiprocess: bool = True, multiinterpreter: bool = False, return_timers: bool = False, device_type: str = 'neuron'*) → List[Dict]:

Benchmarks the model index or individiual model using the provided inputs. If a model index is provided, additional fields such as `pipeline_sizes` and `performance_levels` can be used to filter the models to benchmark. The default behavior is to benchmark all configurations in the model index.

Parameters

- **load_fn** – A function that accepts a model filename and device id, and returns a loaded model. This is automatically passed through the subpackage calls (e.g. `neuronperf.torch.benchmark`).
- **model_filename** (*str*) – A path to a model index from compile or path to an individual model. For CPU benchmarking, a class should be passed that can be instantiated with a default constructor (e.g. `MyModelClass`).
- **inputs** (*list*) – A list of example inputs. If the list contains tuples, they will be destructured on inference to support multiple arguments.
- **batch_sizes** – A list of ints indicating batch sizes that correspond to the inputs. Assumes 1 if not provided.
- **duration** (*float*) – The number of seconds to benchmark each model.
- **n_models** – The number of models to run in parallel. Default behavior runs 1 model and the max number of models possible, determined by a best effort from `device_type`, instance size, or other environment state.
- **pipeline_sizes** – A list of pipeline sizes to use. See *NeuronCore Pipeline*.
- **performance_levels** – A list of performance levels to try. Options are: 0 (max accuracy), 1, 2, 3 (max performance, default). See *Mixed precision and performance-accuracy tuning (neuron-cc)*.
- **workers_per_model** – The number of workers to use per model loaded. If `None`, this is automatically selected.
- **env_setup_fn** – A custom environment setup function to run in each subprocess before model loading. It will receive the benchmarker id and config.
- **setup_fn** – A function that receives the benchmarker id, config, and model to perform last minute configuration before inference.
- **preprocess_fn** – A custom preprocessing function to perform on each input before inference.
- **postprocess_fn** – A custom postprocessing function to perform on each input after inference.

- **multiprocess** (*bool*) – When True, model loading is dispatched to forked subprocesses. Should be left alone unless debugging.
- **multiinterpreter** (*bool*) – When True, benchmarking is performed in a new python interpreter per model. All parameters must be serializable. Overrides multiprocess.
- **return_timers** (*bool*) – When True, the return of this function is a list of tuples `(config, results)` with detailed information. This can be converted to reports with `get_reports(results)`.
- **stats_interval** (*float*) – Collection interval (in seconds) for metrics during benchmarking, such as CPU and memory usage.
- **device_type** (*str*) – This will be set automatically to one of the `SUPPORTED_DEVICE_TYPES`.
- **cost_per_hour** (*float*) – The price of this device / hour. Used to estimate cost / 1 million infs in reports.
- **model_name** (*str*) – A friendly name for the model to use in reports.
- **model_class_name** (*str*) – Internal use.
- **model_class_file** (*str*) – Internal use.
- **verbosity** (*int*) – 0 = error, 1 = info, 2 = debug

Returns A list of benchmarking results.

Return type list[dict]

get_reports(*results*)

Summarizes and combines the detailed results from `neuronperf.benchmark`, when run with `return_timers=True`. One report dictionary is produced per model configuration benchmarked. The list of reports can be fed directly to other reporting utilities, such as `neuronperf.write_csv`.

Parameters

- **results** (*list[tuple]*) – The list of results from `neuronperf.benchmark`.
- **batch_sizes** (*list[int]*) – The batch sizes that correspond to the *inputs* provided to `compile` and `benchmark`. Used to correct throughput values in the reports.

Returns A list of dictionaries that summarize the results for each model configuration.

Return type list[dict]

print_reports(*reports*, *cols=SUMMARY_COLS*, *sort_by='throughput_peak'*, *reverse=False*)

Print a report to the terminal. Example of default behavior:

```
>>> neuronperf.print_reports(reports)
throughput_avg latency_ms_p50 latency_ms_p99 n_models pipeline_size  workers_per_
↪model batch_size model_filename
329.667        6.073          6.109          1        1              2             ␣
↪   1          models/model_b1_p1_83bh3hhs.pt
```

Parameters

- **reports** – Results from *get_reports*.
- **cols** – The columns in the report to be displayed.
- **sort_by** – Sort the cols by the specified key.
- **reverse** – Sort order.

write_csv(*reports: list[dict]*, *filename: str = None*, *cols=REPORT_COLS*)

Write benchmarking reports to CSV file.

Parameters

- **reports** (*list[dict]*) – Results from *neuronperf.get_reports*.
- **filename** (*str*) – Filename to write. If not provided, generated from model_name in report and current timestamp.
- **cols** (*list[str]*) – The columns in the report to be kept.

Returns The filename written.

Return type str

write_json(*reports: list[dict]*, *filename: str = None*)

Writes benchmarking reports to a JSON file.

param list[dict] reports Results from *neuronperf.get_reports*.

param str filename Filename to write. If not provided, generated from model_name in report and current timestamp.

return The filename written.

rtype str

model_index.**append**(**model_indexes: Union[str, dict]*) → dict:

Appends the model indexes non-destructively into a new model index, without modifying any of the internal data.

This is useful if you have benchmarked multiple related models and wish to combine their respective model indexes into a single index.

Model name will be taken from the first index provided. Duplicate configs will be filtered.

Parameters **model_indexes** – Model indexes or paths to model indexes to combine.

Returns A new dictionary representing the combined model index.

Return type dict

model_index.**copy**(*old_index: Union[str, dict]*, *new_index: str*, *new_dir: str*) → str:

Copy an index to a new location. Will rename `old_index` to `new_index` and copy all model files into `new_dir`, updating the index paths.

This is useful for pulling individual models out of a pool.

Returns the path to the new index.

model_index.**create**(*filename*, *input_idx=0*, *batch_size=1*, *pipeline_size=1*, *cast_mode=DEFAULT_CAST*, *compile_s=None*)

Create a new model index from a pre-compiled model.

Parameters

- **filename** (*str*) – The path to the compiled model.
- **input_idx** (*int*) – The index in your inputs that this model should be run on.
- **batch_size** (*int*) – The batch size at compilation for this model.
- **pipeline_size** (*int*) – The pipeline size used at compilation for this model.
- **cast_mode** (*str*) – The casting option this model was compiled with.
- **compile_s** (*float*) – Seconds spent compiling.

Returns A new dictionary representing a model index.

Return type dict

model_index.delete(filename: str):

Deletes the model index and all associated models referenced by the index.

model_index.**filter**(*index: Union[str, dict]*, ***kwargs*) → dict:

Filters provided model index on provided criteria and returns a new index. Each kwarg is a standard (k, v) pair, where k is treated as a filter name and v may be one or more values used to filter model configs.

model_index.**load**(*filename*) → dict:

Load a NeuronPerf model index from a file.

model_index.**move**(*old_index: str*, *new_index: str*, *new_dir: str*) → str:

This is the same as `copy` followed by `delete` on the old index.

model_index.**save**(*model_index*, *filename: str = None*, *root_dir=None*) → str:

Save a NeuronPerf model index to a file.

NeuronPerf Framework Notes

PyTorch

- **Requires: `torch-neuron`**
  - Versions: 1.7.x, 1.8.x, 1.9.x, 1.10.x
- Input to `compile`: `torch.nn.Module`
- Model inputs: `Any`.

TensorFlow 1.x

- **Requires: `tensorflow-neuron`**
  - Versions: All
- Input to `compile`: Path to uncompiled model dir from `saved_model.simple_save`
- Model inputs: Tensors must be provided as `numpy.ndarray`

Note: Although TensorFlow *tensors* must be `ndarray`, this doesn't stop you from wrapping them inside of data structures that traverse process boundaries safely. For example, you can still pass an input `dict` like `{'input_0': np.zeros((2, 1))}`.

TensorFlow 2.x

- **Requires: `tensorflow-neuron`**
  - Versions: All
- Input to `compile`: `tf.keras.Model`
- Model inputs: Tensors must be provided as `numpy.ndarray`

Note: Although TensorFlow *tensors* must be `ndarray`, this doesn't stop you from wrapping them inside of data structures that traverse process boundaries safely. For example, you can still pass an input `dict` like `{'input_0': np.zeros((2, 1))}`.

Apache MXNet (Incubating)

- **Requires: `mxnet-neuron`**
  - Versions 1.5, 1.8
- Input to `compile`: `tuple(sym, args, aux)`
- Inputs: Tensors must be provided as `mxnet.ndarray` or `numpy.ndarray`

NeuronPerf FAQ

Table of contents

- *When should I use NeuronPerf?*
- *When should I **not** use NeuronPerf?*
- *Is NeuronPerf Open Source?*
- *What is the secret to obtaining the best numbers?*
- *What are the "best practices" that NeuronPerf uses?*

When should I use NeuronPerf?

When you want to measure the highest achievable performance for your model with Neuron.

When should I not use NeuronPerf?

When measuring end-to-end performance that includes your network serving stack. Instead, your should compare your e2e numbers to those obtained by NeuronPerf to optimize your serving overhead.

Is NeuronPerf Open Source?

Yes. You can `download the source here`.

What is the secret to obtaining the best numbers?

There is no secret sauce. NeuronPerf follows best practices.

What are the "best practices" that NeuronPerf uses?

- These vary slightly by framework and how your model was compiled
- For a model compiled for a single NeuronCore (DataParallel):
  - To maximize throughput, for `N` models, use `2 * N` worker threads
  - To minimize latency, use 1 worker thread per model
- Use a new Python process for each model to avoid GIL contention
- Ensure you benchmark long enough for your numbers to stabilize
- Ignore outliers at the start and end of inference benchmarking

Compilation issues

Model fails to compile

Please file a bug with as much information as possible.

Benchmarking Issues

Benchmarking terminates early with errors

- **Scroll up and read the output. Most likely causes are:**
  - invalid input shapes or
  - not enough memory to load the requested number of model copies on the device. Try passing `n_models=1` to `benchmark` again to test for memory issues.

Other Issues or Feature Requests

Please file a bug on Github.

SETUP GUIDE

This section walks you through the various options to install Neuron. You have to install Neuron on Trainium and Inferentia powered instances to enable deep-learning acceleration.

Inf1

PyTorch Neuron

TensorFlow Neuron

MXNet Neuron

Trn1

PyTorch Neuron

Important: AutoScalingGroups is currently not supported on Trn1 and will be added soon.

To launch a Trn1 cluster you can use AWS ParallelCluster, please see example.

Note: Neuron Driver installed on Deep Learning AMI (DLAMI) with Conda does not support Trn1.

If you want to use DLAMI with Conda, please make sure to uninstall `aws-neuron-dkms` and install `aws-neuronx-dkms` before using Neuron on DLAMI with Conda.

CHAPTER

FIFTEEN

DEPLOY CONTAINERS WITH NEURON

In this section you will find resources to help you use containers for your accelerated deep learning model acceleration on top of Inferentia and Trainium enabled instances.

The section is organized based on the target deployment environment and use case. In most cases, it is recommended to use a preconfigured Deep Learning Container (DLC) from AWS. Each DLC is pre-configured to have all of the Neuron components installed and is specific to the chosen ML Framework.

Locate Neuron DLC image

Latest Neuron DLC images

Find latest Neuron DLC images.

Locate specific Neuron DLC release

In the DLC release page do a search for Neuron to get the ECR repo location of specific Neuron DLC release.

Getting Started

Training

Launch Trn1 Instance

- Please follow the instructions at launch an Amazon EC2 Instance to Launch an Trn1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Trn1 instances sizes and pricing see Trn1 web page.
- Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Amazon Linux 2 AMI(HVM) - Kernel 5.10.
- When launching a Trn1, please adjust your primary EBS volume size to a minimum of 512GB.
- After launching the instance, follow the instructions in Connect to your instance to connect to the instance

Important: AutoScalingGroups is currently not supported on Trn1 and will be added soon.

To launch a Trn1 cluster you can use AWS ParallelCluster, please see example.

Note: Neuron Driver installed on Deep Learning AMI (DLAMI) with Conda does not support Trn1.

If you want to use DLAMI with Conda, please make sure to uninstall `aws-neuron-dkms` and install `aws-neuronx-dkms` before using Neuron on DLAMI with Conda.

Install Drivers

```
# Configure Linux for Neuron repository updates

sudo tee /etc/yum.repos.d/neuron.repo > /dev/null <<EOF
[neuron]
name=Neuron YUM Repository
baseurl=https://yum.repos.neuron.amazonaws.com
enabled=1
metadata_expire=0
EOF
sudo rpm --import https://yum.repos.neuron.amazonaws.com/GPG-PUB-KEY-AMAZON-AWS-NEURON.

Install Docker

```
sudo yum install -y docker.io
sudo usermod -aG docker $USER

Logout and log back in to refresh membership.
```

Verify Docker

```
docker run hello-world
```

Expected result:

```
Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
1. The Docker client contacted the Docker daemon.
2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
(amd64)
3. The Docker daemon created a new container from that image which runs the
executable that produces the output you are currently reading.
4. The Docker daemon streamed that output to the Docker client, which sent it
to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
$ docker run -it ubuntu bash

Share images, automate workflows, and more with a free Docker ID:
https://hub.docker.com/

For more examples and ideas, visit:
https://docs.docker.com/get-started/
```

Verify Neuron Component

Once the environment is setup, a container can be started with –device=/dev/neuron# to specify desired set of Inferentia/Trainium devices to be exposed to the container. To find out the available neuron devices on your instance, use the command `ls /dev/neuron*`.

When running neuron-ls inside a container, you will only see the set of exposed Trainiums. For example:

```
docker run --device=/dev/neuron0 neuron-test neuron-ls

Would produce the following output in trn1.32xlarge:

::

   +--------+--------+--------+---------+
   | NEURON | NEURON | NEURON |   PCI   |
   | DEVICE | CORES  | MEMORY |   BDF   |
   +--------+--------+--------+---------+
   | 0      | 2      | 32 GB  | 10:1c.0 |
   +--------+--------+--------+---------+
```

Build and Run Docker Image

Run Tutorial

Run training in Pytorch Neuron container

Inference

Launch Inf1 Instance

- Please follow the instructions at launch an Amazon EC2 Instance to Launch an Inf1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Inf1 instances sizes and pricing see Inf1 web page.
- Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Amazon Linux 2 AMI(HVM) - Kernel 5.10
- After launching the instance, follow the instructions in Connect to your instance to connect to the instance

Install Drivers

```
# Configure Linux for Neuron repository updates
sudo tee /etc/yum.repos.d/neuron.repo > /dev/null <<EOF
[neuron]
name=Neuron YUM Repository
baseurl=https://yum.repos.neuron.amazonaws.com
enabled=1
metadata_expire=0
EOF
sudo rpm --import https://yum.repos.neuron.amazonaws.com/GPG-PUB-KEY-AMAZON-AWS-NEURON.
↪PUB

# Update OS packages
sudo yum update -y

##########################################################################################
↪#######################
# To install or update to Neuron versions 1.19.1 and newer from previous releases:

Run Tutorial

Run inference in pytorch neuron container

Kubernetes Getting Started

Prerequisite

- Working kubernetes cluster
- Inf1/Trn1 instances as worker nodes with attached roles allowing: * ECR read access policy to retrieve container images from ECR: **arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly**
- tutorial-docker-env-setup: to install required packages in the worker nodes. With EKS, the EKS optimized accelarated AMI has the necessary neuron components installed
- Kubernetes node object has instance-type set to inf1/trn1 types. For ex, `"node.kubernetes.io/instance-type": "inf1.2xlarge"` or `"node.kubernetes.io/instance-type": "trn1.2xlarge"`

Deploy Neuron Device Plugin

Neuron device plugin exposes Neuron cores & devices to kubernetes as a resource. aws.amazon.com/neuroncore, aws.amazon.com/neurondevice, aws.amazon.com/neuron are the resources that the neuron device plugin registers with the kubernetes. aws.amazon.com/neuroncore is used for allocating neuron cores to the container. aws.amazon.com/neurondevice is used for allocating neuron devices to the container. When neurondevice is used all the cores belonging to the device will be allocated to container. aws.amazon.com/neuron also allocates neurondevices and this exists just to be backward compatible with already existing installations. aws.amazon.com/neurondevice is the recommended resource for allocating devices to the container.

- Make sure prequisite are satisified
- Download the neuron device plugin yaml file. `k8s-neuron-device-plugin.yml`
- Download the neuron device plugin rbac yaml file. This enables permissions for device plugin to update the node and Pod annotations. `k8s-neuron-device-plugin-rbac.yml`
- Apply the Neuron device plugin as a daemonset on the cluster with the following command

  ```
  kubectl apply -f k8s-neuron-device-plugin-rbac.yml
  kubectl apply -f k8s-neuron-device-plugin.yml
  ```

- Verify that neuron device plugin is running

```
kubectl get ds neuron-device-plugin-daemonset --namespace kube-system
```

Expected result (with 2 nodes in cluster):

```
NAME                              DESIRED   CURRENT   READY   UP-TO-DATE  ␣
↪AVAILABLE   NODE SELECTOR   AGE
neuron-device-plugin-daemonset    2         2         2       2           ␣
↪2           <none>          27h
```

- Verify that the node has allocatable neuron cores and devices with the following command

```
kubectl get nodes "-o=custom-columns=NAME:.metadata.name,NeuronCore:.
↪status.allocatable.aws\.amazon\.com/neuroncore"
```

Expected result:

```
NAME                                          NeuronCore
ip-192-168-65-41.us-west-2.compute.internal   32
ip-192-168-87-81.us-west-2.compute.internal   32
```

```
kubectl get nodes "-o=custom-columns=NAME:.metadata.name,NeuronDevice:.
↪status.allocatable.aws\.amazon\.com/neurondevice"
```

Expected result:

```
NAME                                          NeuronDevice
ip-192-168-65-41.us-west-2.compute.internal   16
ip-192-168-87-81.us-west-2.compute.internal   16
```

Deploy Neuron Scheduler Extension

Neuron scheduler extension is required for scheduling pods that require more than one Neuron core or device resource. Refer k8s-neuron-scheduler-flow for details on how the neuron scheduler extension works. Neuron scheduler extension filter out nodes with non-contiguous core/device ids and enforces allocation of contiguous core/device ids for the PODs requiring it.

Multiple Scheduler Approach

In cluster environments where there is no access to default scheduler, the neuron scheduler extension can be used with another scheduler. A new scheduler is added (along with the default scheduler) and then the pod's that needs to run the neuron workload use this new scheduler. Neuron scheduler extension is added to this new scheduler. EKS natively does not yet support the neuron scheduler extension and so in the EKS environment this is the only way to add the neuron scheduler extension.

- Make sure Neuron device plugin is running
- Download the my scheduler `my-scheduler.yml`
- Download the scheduler extension `k8s-neuron-scheduler-eks.yml`
- Apply the neuron-scheduler-extension

```
kubectl apply -f k8s-neuron-scheduler-eks.yml
```

- Get the neuron scheduler extension cluster ip

```
kubectl get service --namespace kube-system k8s-neuron-scheduler -o␣
↪jsonpath='{.spec.clusterIP}'
```

- Modify the urlPrefix in my-scheduler.yml. Replace 127.0.0.1 with cluster ip above.

```
"urlPrefix": "http://127.0.0.1:12345 to "urlPrefix": "http://<cluster-ip-
↪from-above>:12345
```

- Apply the modified my-scheduler.yml

```
kubectl apply -f my-scheduler.yml
```

- Check there are no errors in the my-scheduler pod logs and the k8s-neuron-scheduler pod is bound to a node

```
kubectl logs -n kube-system my-scheduler-79bd4cb788-hq2sq
```

```
I1012 15:30:21.629611       1 scheduler.go:604] "Successfully bound pod to␣
↪node" pod="kube-system/k8s-neuron-scheduler-5d9d9d7988-xcpqm" node="ip-
↪192-168-2-25.ec2.internal" evaluatedNodes=1 feasibleNodes=1
```

- When running new pod's that need to use the neuron scheduler extension, make sure it uses the my-scheduler as the scheduler. Sample pod spec is below

```
apiVersion: v1
kind: Pod
metadata:
name: <POD_NAME>
spec:
restartPolicy: Never
schedulerName: my-scheduler
containers:
    - name: <POD_NAME>
    command: ["<COMMAND>"]
    image: <IMAGE_NAME>
    resources:
        limits:
        cpu: "4"
        memory: 4Gi
        aws.amazon.com/neuroncore: 9
        requests:
        cpu: "1"
        memory: 1Gi
```

- Once the neuron workload pod is run, make sure logs in the k8s neuron scheduler has successfull filter/bind request

```
kubectl logs -n kube-system k8s-neuron-scheduler-5d9d9d7988-xcpqm
```

```
2022/10/12 15:41:16 POD nrt-test-5038 fits in Node:ip-192-168-2-25.ec2.

```

(continued on next page)

(continued from previous page)

```
2022/10/12 15:41:16 Finished executing Bind Request...
```

Default Scheduler Approach

- Make sure Neuron device plugin is running
- Download the scheduler config map `k8s-neuron-scheduler-configmap.yml`
- Download the scheduler extension `k8s-neuron-scheduler.yml`
- Enable the kube-scheduler with option to use configMap for scheduler policy. In your cluster.yml Please update the spec section with the following

```
spec:
  kubeScheduler:
  usePolicyConfigMap: true
```

- Launch the cluster

```
kops create -f cluster.yml
kops create secret --name neuron-test-1.k8s.local sshpublickey admin -i ~/.
↪ssh/id_rsa.pub
kops update cluster --name neuron-test-1.k8s.local --yes
```

- Apply the k8s-neuron-scheduler-configmap.yml [Registers neuron-scheduler-extension with kube-scheduler]

```
kubectl apply -f k8s-neuron-scheduler-configmap.yml
```

- Launch the neuron-scheduler-extension

```
kubectl apply -f k8s-neuron-scheduler.yml
```

Tutorials

Training

This document is relevant for: `Trn1`

15.1 Run training in Pytorch Neuron container

Table of Contents

- *Overview*
- *Setup Environment*

15.1.1 Overview

This tutorial demonstrates how to run a pytorch container on an trainium instance.

By the end of this tutorial you will be able to run simple mlp training using the container

You will use an trn1.2xlarge to test your Docker configuration for Trainium.

To find out the available neuron devices on your instance, use the command `ls /dev/neuron*`.

15.1.2 Setup Environment

1. **Launch an Trn1 Instance**

   - Please follow the instructions at launch an Amazon EC2 Instance to Launch an Trn1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Trn1 instances sizes and pricing see Trn1 web page.
   - Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Amazon Linux 2 AMI(HVM) - Kernel 5.10.
   - When launching a Trn1, please adjust your primary EBS volume size to a minimum of 512GB.
   - After launching the instance, follow the instructions in Connect to your instance to connect to the instance

   Important: AutoScalingGroups is currently not supported on Trn1 and will be added soon.

   To launch a Trn1 cluster you can use AWS ParallelCluster, please see example.

   Note: Neuron Driver installed on Deep Learning AMI (DLAMI) with Conda does not support Trn1.

   If you want to use DLAMI with Conda, please make sure to uninstall `aws-neuron-dkms` and install `aws-neuronx-dkms` before using Neuron on DLAMI with Conda.

2. Set up docker environment according to tutorial-docker-env-setup

3. A sample Dockerfile for for torch-neuron can be found here trainium-dlc-dockerfile. This dockerfile needs the mlp train script found here mlp-train

With the files in a dir, build the image with the following command:

```
docker build . -f Dockerfile.pt -t neuron-container:pytorch
```

Run the following command to start the container

```
docker run -it --name pt-cont --net=host --device=/dev/neuron0 neuron-container:pytorch␣
↪python3 /opt/ml/mlp_train.py
```

This document is relevant for: `Trn1`

This document is relevant for: `Trn1`

15.2 Deploy a simple mlp training script as a Kubernetes job

This tutorial uses mlp train as a teaching example on how to deploy an training application using Kubernetes on the Trn1 instances.

15.2.1 Prerequisite:

- tutorial-k8s-env-setup-for-neuron: to setup k8s support on your cluster.
- Trn1 instances as worker nodes with attached roles allowing:
  - ECR read access policy to retrieve container images from ECR: **arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly**
- Have a container image that is build using *Run training in Pytorch Neuron container*

15.2.2 Deploy a mlp training image

1. Create a file named *mlp_train.yaml* with the contents below.

Note: In the image: add the appropriate location of the image

```
apiVersion: v1
kind: Pod
metadata:
  name: trn1-mlp
spec:
  restartPolicy: Never
  schedulerName: default-scheduler
  hostNetwork: true
  nodeSelector:
    beta.kubernetes.io/instance-type: trn1.32xlarge
    beta.kubernetes.io/instance-type: trn1.2xlarge
  containers:
    - name: trn1-mlp
      command: ["/usr/local/bin/python3"]
      args:  ["/opt/ml/mlp_train.py"]
      image: 647554078242.dkr.ecr.us-east-1.amazonaws.com/sunda-pt:k8s_mlp_0907
      imagePullPolicy: IfNotPresent
      env:
      - name: NEURON_RT_LOG_LEVEL
        value: "INFO"
      resources:
        limits:
          aws.amazon.com/neuron: 2
        requests:
          aws.amazon.com/neuron: 2
```

2. Deploy the pod.

```
kubectl apply -f mlp_train.yaml
```

3. Check the logs to make sure training completed

```
kubectl logs <pod name>

Your log should have the following
```

```
Final loss is 0.1977
----------End Training ---------------
```

This document is relevant for: `Trn1`

Inference

This document is relevant for: `Inf1`

15.3 Run inference in pytorch neuron container

Table of Contents

- *Overview*
- *Setup Environment*

15.3.1 Overview

This tutorial demonstrates how to run a pytorch DLC on an inferentia instance.

By the end of this tutorial you will be able to run the inference using the container

You will use an inf1.2xlarge to test your Docker configuration for Inferentia.

To find out the available neuron devices on your instance, use the command `ls /dev/neuron*`.

15.3.2 Setup Environment

1. **Launch an Inf1 Instance**
    - Please follow the instructions at launch an Amazon EC2 Instance to Launch an Inf1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Inf1 instances sizes and pricing see Inf1 web page.
    - Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Amazon Linux 2 AMI(HVM) - Kernel 5.10
    - After launching the instance, follow the instructions in Connect to your instance to connect to the instance
2. Set up docker environment according to tutorial-docker-env-setup

3. A sample Dockerfile for for torch-neuron can be found here inference-dlc-dockerfile. This dockerfile needs the torchserve entrypoint found here torchserve-neuron and torchserve config.properties found here torchserve-config-properties.

With the files in a dir, build the image with the following command:

```
docker build . -f Dockerfile.pt -t neuron-container:pytorch
```

Run the following command to start the container

```
docker run -itd --name pt-cont -p 80:8080 -p 8081:8081 --device=/dev/neuron0 neuron-
↪container:pytorch /usr/local/bin/entrypoint.sh -m 'pytorch-resnet-neuron=https://aws-
↪dlc-sample-models.s3.amazonaws.com/pytorch/Resnet50-neuron.mar' -t /home/model-server/
↪config.properties
```

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

15.4 Deploy a TensorFlow Resnet50 model as a Kubernetes service

This tutorial uses Resnet50 model as a teaching example on how to deploy an inference application using Kubernetes on the Inf1 instances.

15.4.1 Prerequisite:

- tutorial-k8s-env-setup-for-neuron: to setup k8s support on your cluster.
- Inf1 instances as worker nodes with attached roles allowing:
  - ECR read access policy to retrieve container images from ECR: **arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly**
  - S3 access to retrieve saved_model from within tensorflow serving container.

15.4.2 Deploy a TensorFlow Serving application image

A trained model must be compiled to an Inferentia target before it can be deployed on Inferentia instances. To continue, you will need a Neuron optimized TensorFlow model saved in Amazon S3. If you don't already have a SavedModel, please follow the tutorial for creating a Neuron compatible ResNet50 model and upload the resulting SavedModel to S3.

ResNet-50 is a popular machine learning model used for image classification tasks. For more information about compiling Neuron models, see The AWS Inferentia Chip With DLAMI in the AWS Deep Learning AMI Developer Guide.

The sample deployment manifest manages a pre-built inference serving container for TensorFlow provided by AWS Deep Learning Containers. Inside the container is the AWS Neuron Runtime and the TensorFlow Serving application. A complete list of pre-built Deep Learning Containers optimized for Neuron is maintained on GitHub under Available Images. At start-up, the DLC will fetch your model from Amazon S3, launch Neuron TensorFlow Serving with the saved model, and wait for prediction requests.

The number of Neuron devices allocated to your serving application can be adjusted by changing the *aws.amazon.com/neuron* resource in the deployment yaml. Please note that communication between TensorFlow Serving and the Neuron runtime happens over GRPC, which requires passing the *IPC_LOCK* capability to the container.

1. Create a file named *rn50_deployment.yaml* with the contents below. Update the region-code and model path to match your desired settings. The model name is for identification purposes when a client makes a request to the TensorFlow server. This example uses a model name to match a sample ResNet50 client script that will be used in a later step for sending prediction requests.

Note:

1. Replace the s3 bucket name in model_base_path arg in the file with the location of the where the saved model was stored in s3.
2. In the image: add the appropriate location of the DLC tensorflow image

```

          command:
            - /usr/local/bin/entrypoint.sh
          args:
            - --port=8500
            - --rest_api_port=9000
            - --model_name=resnet50_neuron
            - --model_base_path=s3://your-bucket-of-models/resnet50_neuron/
          ports:
            - containerPort: 8500
            - containerPort: 9000
          imagePullPolicy: IfNotPresent
          env:
            - name: AWS_REGION
              value: "us-east-1"
            - name: S3_USE_HTTPS
              value: "1"
            - name: S3_VERIFY_SSL
              value: "0"
            - name: S3_ENDPOINT
              value: s3.us-east-1.amazonaws.com
            - name: AWS_LOG_LEVEL
              value: "3"
```

(continues on next page)

(continued from previous page)

```
          resources:
            limits:
              cpu: 4
              memory: 4Gi
              aws.amazon.com/neuron: 1
            requests:
              cpu: "1"
              memory: 1Gi
          securityContext:
            capabilities:
              add:
                - IPC_LOCK
```

2. Deploy the model.

```
kubectl apply -f rn50_deployment.yaml
```

3. Create a file named *rn50_service.yaml* with the following contents. The HTTP and gRPC ports are opened for accepting prediction requests.

```
kind: Service
apiVersion: v1
metadata:
  name: k8s-neuron-test
  labels:
    app: k8s-neuron-test
spec:
  type: ClusterIP
  ports:
    - name: http-tf-serving
      port: 8500
      targetPort: 8500
    - name: grpc-tf-serving
      port: 9000
      targetPort: 9000
  selector:
    app: k8s-neuron-test
    role: master
```

4. Create a Kubernetes service for your TensorFlow model Serving application.

```
kubectl apply -f rn50_service.yaml
```

15.4.3 Make predictions against your TensorFlow Serving service

1. To test locally, forward the gRPC port to the *k8s-neuron-test* service.

```
kubectl port-forward service/k8s-neuron-test 8500:8500 &
```

2. Create a Python script called *tensorflow-model-server-infer.py* with the following content. This script runs inference via gRPC, which is service framework.

```
import numpy as np
import grpc
import tensorflow as tf
from tensorflow.keras.preprocessing import image
from tensorflow.keras.applications.resnet50 import preprocess_input
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_service_pb2_grpc
from tensorflow.keras.applications.resnet50 import decode_predictions

if __name__ == '__main__':
    channel = grpc.insecure_channel('localhost:8500')
    stub = prediction_service_pb2_grpc.PredictionServiceStub(channel)
    img_file = tf.keras.utils.get_file(
        "./kitten_small.jpg",
        "https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/docs/images/
↪kitten_small.jpg")
    img = image.load_img(img_file, target_size=(224, 224))
    img_array = preprocess_input(image.img_to_array(img)[None, ...])
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'resnet50_inf1'
    request.inputs['input'].CopyFrom(
        tf.make_tensor_proto(img_array, shape=img_array.shape))
    result = stub.Predict(request)
    prediction = tf.make_ndarray(result.outputs['output'])
    print(decode_predictions(prediction))
```

3. Run the script to submit predictions to your service.

```
python3 tensorflow-model-server-infer.py

Your output should look like the following:
```

```
[[(u'n02123045', u'tabby', 0.68817204), (u'n02127052', u'lynx', 0.12701613), (u'n02123159
↪', u'tiger_cat', 0.08736559), (u'n02124075', u'Egyptian_cat', 0.063844085), (u
↪'n02128757', u'snow_leopard', 0.009240591)]]
```

15.5 Deploy Neuron Container on EC2

Table of Contents

- *Description*
- *Setup Environment*

15.5.1 Description

You can use the Neuron version of the AWS Deep Learning Containers to run inference on inf1 instances. In this developer flow, you provision an EC2 inf1 instance using a Deep Learning AMI (DLAMI), pull the container image with the Neuron version of the desired framework, and run the container as a server for the already compiled model. This developer flow assumes the model has already has been compiled through a compilation developer flow

15.5.2 Setup Environment

1. **Launch an Inf1 Instance**
   - Please follow the instructions at launch an Amazon EC2 Instance to Launch an Inf1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Inf1 instances sizes and pricing see Inf1 web page.
   - Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Ubuntu 18 AMI or Amazon Linux 2 AMI, you can also choose Ubuntu 18 or Amazon Linux 2 Deep Learning AMI (DLAMI)
   - After launching the instance, follow the instructions in Connect to your instance to connect to the instance
2. Once you have your EC2 environment set according to tutorial-docker-env-setup, you can build and run a Neuron container using the how-to-build-neuron-container section above.

Note: Prior to running the container, make sure that the Neuron runtime on the instance is turned off, by running the command:

```
sudo service neuron-rtd stop
```

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

15.6 Deploy Neuron Container on Elastic Container Service (ECS)

Table of Contents

- *Description*
- *Setup Environment*

15.6.1 Description

You can use the Neuron version of the AWS Deep Learning Containers to run inference on Amazon Elastic Container Service (ECS). In this developer flow, you set up an ECS cluster with inf1 instances, create a task description for your inference service and deploy it to your cluster. This developer flow assumes:

1. The model has already been compiled through *Compilation with Framework API on EC2 instance* or through *Compilation with Sagemaker Neo*.
2. You already set up your container to retrieve it from storage.

15.6.2 Setup Environment

1. **Set up an Amazon ECS cluster:** Follow the instructions on Setting up Amazon ECS for Deep Learning Containers
2. **Define an Inference Task:** Use the instruction on the DLC Inference on ECS Tutorial to define a task and create a service for the appropriate framework.

   When creating tasks for inf1 instances on ECS, be aware of the considerations and requirements listed in Working with inference workloads on Amazon ECS.
3. Use the container image created using how-to-build-neuron-container as the `image` in your task definition.

Note: Before deploying your task definition to your ECS cluster, make sure to push the image to ECR. Refer to Pushing a Docker image for more information.

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

15.7 Deploy Neuron Container on Elastic Kubernetes Service (EKS)

Table of Contents

- *Description*
- *Setup Environment*
  - *Self-managed Kubernetes*

15.7.1 Description

You can use the Neuron version of the AWS Deep Learning Containers to run inference on Amazon Elastic Kubernetes Service (EKS). In this developer flow, you set up an EKS cluster with Inf1 instances, create a Kubernetes manifest for your inference service and deploy it to your cluster. This developer flow assumes:

1. The model has already been compiled through *Compilation with Framework API on EC2 instance* or through *Compilation with Sagemaker Neo*.
2. You already set up your container to retrieve it from storage.

15.7.2 Setup Environment

1. **Install pre-requisits:** Follow these instruction to install or upgrade the *eksctl* command line utility on your local computer.

   Follow these instruction to install *kubectl* in the same computer. *kubectl* is a command line tool for working with Kubernetes clusters.

2. Follow the instructions in this EKS documentation link to set up AWS Inferentia on your EKS cluster. Using the YML deployment manifest shown in the same link, replace the *image* in the *containers* specification with the one you built using how-to-build-neuron-container above.

   Note: Before deploying your task definition to your EKS cluster, make sure to push the image to ECR. Refer to Pushing a Docker image for more information.

Self-managed Kubernetes

Please refer to tutorial-k8s-env-setup-for-neuron. In *Deploy a TensorFlow Resnet50 model as a Kubernetes service*, the container image referenced in the YML manifest is created using how-to-build-neuron-container.

This document is relevant for: `Inf1`

15.8 Bring Your Own Neuron Container to Sagemaker Hosting

Table of Contents

- *Description*
- *Setup Environment*

15.8.1 Description

You can use a SageMaker Notebook or an EC2 instance to compile models and build your own containers for deployment on SageMaker Hosting using ml.inf1 instances. In this developer flow, you provision a Sagemaker Notebook or an EC2 instance to train and compile your model to Inferentia. Then you deploy your model to SageMaker Hosting using the SageMaker Python SDK. Follow the steps bellow to setup your environment. Once your environment is set you'll be able to follow the *BYOC HuggingFace pretrained BERT container to Sagemaker Tutorial* .

15.8.2 Setup Environment

1. **Create a Compilation Instance:** If using an **EC2 instance for compilation** you can use an Inf1 instance to compile and test a model. Follow these steps to launch an Inf1 instance:

   - Please follow the instructions at launch an Amazon EC2 Instance to Launch an Inf1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Inf1 instances sizes and pricing see Inf1 web page.
   - Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Ubuntu 18 AMI or Amazon Linux 2 AMI, you can also choose Ubuntu 18 or Amazon Linux 2 Deep Learning AMI (DLAMI)
   - After launching the instance, follow the instructions in Connect to your instance to connect to the instance

   If using an **SageMaker Notebook for compilation**, follow the instructions in Get Started with Notebook Instances to provision the environment.

   It is recommended that you start with an ml.c5.4xlarge instance for the compilation. Also, increase the volume size of you SageMaker notebook instance, to accomodate the models and containers built locally. A volume of 10GB is sufficient.

   > **Note:** To compile the model in the SageMaker Notebook instance, you'll need to update the conda environments to include the Neuron Compiler and Neuron Framework Extensions. Follow the installation guide on the section how-to-update-to-latest-Neuron-Conda-Env to update the environments.

2. **Set up the environment to compile a model, build your own container and deploy:** To compile your model on EC2 or SageMaker Notebook, follow the *Set up a development environment* section on the EC2 *Setup Environment* documentation.

   Refer to Adapting Your Own Inference Container documentation for information on how to bring your own containers to SageMaker Hosting.

   Make sure to add the **AmazonEC2ContainerRegistryPowerUser** role to your IAM role ARN, so you're able to build and push containers from your SageMaker Notebook instance.

   > **Note:** The container image can be created using how-to-build-neuron-container.

FAQ, Troubleshooting and Release Note

This document is relevant for: `Inf1`, `Trn1`

15.9 Neuron Containers FAQ

Table of Contents

- *Where can I find DLC images*
- *What is OCI Neuron Hook and do we need that*
- *What container runtimes are supported*
- *How to expose Neuron Devices to Container*
- *How to expose Neuron Cores to Container*
- *Can Neuron Devices be shared by different Containers running in the same Host*
- *Can Neuron Cores be shared by different Containers running in the same Host*
- *When would you use Neuron K8 Scheduler Extension*
- *How to add EFA devices to the container*
- *Can distributed training jobs be run without EFA devices in container*

15.9.1 Where can I find DLC images

- The Inference/Training DLC images can be found here.
- In the DLC release page do a search for neuron to get the ECR repo location of specific neuron DLC release.

15.9.2 What is OCI Neuron Hook and do we need that

Neuron devices are exposed to the containers using the –device option in the docker run command. Docker runtime (runc) does not yet support the ALL option to expose all neuron devices to the container.

With OCI neuron hook support is added to expose ALL devices to container using an environment variable, "AWS_NEURON_VISIBLE_DEVICES=ALL". For more details please refer oci neuron hook

In Kubernetes, if we are using the device plugin version 1.7 & below, then the oci neuron hook is needed. If using device plugin version >= 1.8 then oci neuron hook is not needed

15.9.3 What container runtimes are supported

Neuron containers have been tested to work with docker, containerd, cri-o runtimes without any changes. If the oci neuron hook is used then they need to be enabled in the runtime config. For more details please refer oci neuron hook

15.9.4 How to expose Neuron Devices to Container

Neuron Device: Represents the number of Inferentia/Trainium chips in the instance. Refer Container Devices for more details

15.9.5 How to expose Neuron Cores to Container

Neuron Core: Represents the number of Neuron Cores in the instance. Refer Container Cores for more details. Each Inferentia Chip has 4 Neuron Cores and each Trainium chip has 2 Neuron Cores. When the devices are exposed to the containers all the cores in the device are available for use in the container. Please refer *Neuron Runtime Configuration* to see how the environment variables NEURON_RT_VISIBLE_CORES and NEURON_RT_NUM_CORES can be used to assign core to containers

15.9.6 Can Neuron Devices be shared by different Containers running in the same Host

Yes, except in Kubernetes environment where the devices cannot be shared

15.9.7 Can Neuron Cores be shared by different Containers running in the same Host

No

15.9.8 When would you use Neuron K8 Scheduler Extension

The neuron cores/devices that are exposed to the container needs to be contiguous. The kubernetes device plugin does not guarantee the devices to be contiguous. The K8 Neuron Scheduler Extension takes care of assigning contiguous devices to the containers.

15.9.9 How to add EFA devices to the container

The EFA devices are exposed to the container using the –device option

```
--device /dev/infiniband/uverbs0
```

In the kubernetes environment the EFA device plugin is used to detect and advertise EFA interfaces.

:: kubectl apply -f https://raw.githubusercontent.com/aws-samples/aws-efa-eks/main/manifest/efa-k8s-device-plugin.yml

Application can use the resource type vpc.amazonaws.com/efa in a pod request spec

```
vpc.amazonaws.com/efa: 4
```

15.9.10 Can distributed training jobs be run without EFA devices in container

No. For distributed training jobs in Trainium all the EFA inrerfaces in trn1.32xlarge needs to be exposed to the containers

This document is relevant for: `Inf1`, `Trn1`

This document is relevant for: `Inf1`, `Trn1`

15.10 Troubleshooting Neuron Containers

This document aims to provide more information on how to fix issues you might encounter while using the Neuron Containers. For each issue we will provide an explanation of what happened and what can potentially correct the issue.

If your issue is not listed below or you have a more nuanced problem, contact us via issues posted to this repo, the AWS Neuron developer forum, or through AWS support.

Neuron Container includes the following Neuron Components. For issues relating to these components inside the container refer the individual component troubleshooting guides *Troubleshooting Guide*

- Neuron Runtime/Driver
- Pytorch/Tenosrflow/MXNet frameworks
- Libfabric/EFA

The following are container specific issues

15.10.1 Neuron Device Not found

The neuron container expects the neuron devices to be exposed to the container as referenced in container-devices.

Please look at the container logs to see messages like below

```
2022-Sep-08 17:55:23.0768    19:19    ERROR  TDRV:tdrv_get_dev_info
↪ No neuron device available
```

If the above message is seen then devices are not exposed to container

Solution

- Refer container-devices and make sure the devices are exposed to container
- If specific cores are being used refer container-cores and make sure the cores are exposed to container
- In kubernetes environment refer k8s-specify-devices or k8s-specify-cores to make sure neuron devices/cores are there in pods container spec

15.10.2 Contiguous Device ID's

Neuron runtime expects the inferentia/trainium device id's to be contigious. If the device id's are not contiguous you might see error messages like below

```
2022-Sep-08 21:52:11.0307     7:7     ERROR  TDRV:tdrv_init_mla_phase1
↪ Could not open the nd1
```

```
2022-Sep-08 23:00:05.0667     8:8     ERROR   NRT:nrt_allocate_neuron_cores
↪ Neuron cores are not contiguous
```

Solution

- In the docker run command make sure the devices specified using –device are all contiguous
- If oci neuron hook is used and the env variable AWS_NEURON_VISIBLE_DEVICES is used then make sure the

devices specified are all contiguous * In kubernetes environment with just the neuron device plugin running there is no guarantee that the devices allocated will be contiguous. Make sure to run the neuron scheduler extension as specified in neuron-k8-scheduler-ext

15.11 Neuron Containers Release Notes

Table of contents

- *Neuron 2.5.0*
- *Neuron 2.4.0*
- *Neuron 2.3.0*
- *Neuron 1.19.0*
- *Neuron 1.16.0*

15.11.1 Neuron 2.5.0

Date: 11/07/2022

- Neuron now supports trn1-based training in Sagemaker and Deep Learning Containers using PyTorch. Find Neuron DLC containers here: https://github.com/aws/deep-learning-containers/blob/master/available_images.md#neuron-containers

15.11.2 Neuron 2.4.0

Date: 10/27/2022

- Neuron now supports Kubernetes work scheduling at the level of NeuronCore. Updates on how to use the new core allocation method is captured in the Kubernetes documentation on this site.

15.11.3 Neuron 2.3.0

Date: 10/10/2022

- Now supporting TRN1 and INF1 EC2 instance types as part of Neuron. There is an optional aws-neuronx-oci-hooks package users may install for conveince that supports use of the AWS_NEURON_VISIBLE_DEVICES environment variable when launching containers. New DLC containers will be coming soon in support of training workloads on TRN1.

15.11.4 Neuron 1.19.0

Date: 04/29/2022

- Neuron Kubernetes device driver plugin now can figure out communication with the Neuron driver without the *oci hooks*. Starting with *Neuron 1.19.0* release, installing `aws-neuron-runtime-base` and `oci-add-hooks` are no longer a requirement for Neuron Kubernetes device driver plugin.

15.11.5 Neuron 1.16.0

Date: 10/27/2021

New in this release

- Starting with Neuron 1.16.0, use of Neuron ML Frameworks now comes with an integrated Neuron Runtime as a library, as a result it is no longer needed to deploy `neuron-rtd`. Please visit neuron-containers for more information.
- When using containers built with components from Neuron 1.16.0, or newer, please use `aws-neuron-dkms` version 2.1 or newer and the latest version of `aws-neuron-runtime-base`. Passing additional system capabilities is no longer required.

15.12.1 Introduction

This document lists the current release notes for AWS Neuron Kubernetes (k8) components. Neuron K8 components include a device plugin and a scheduler extension to assist with deployment and management of inf1 nodes within Kubernetes clusters. Both components are offered as pre-built containers in Public ECR and ready for deployment.

- **Device Plugin:** public.ecr.aws/neuron/neuron-device-plugin:2.0.0.0
- **Neuron Scheduler:** public.ecr.aws/neuron/neuron-scheduler:2.0.0.0

It's recommended to pin the version of the components used and to never use the "latest" tag. To get the list of image tags, please refer to these notes or check the image tags on the repo directly.

To Pull the Images from ECR:

```
docker pull  public.ecr.aws/neuron/neuron-device-plugin:2.0.0.0
docker pull  public.ecr.aws/neuron/neuron-scheduler:2.0.0.0
```

15.12.2 Neuron K8 release [2.1.0.0]

Date: 10/27/2022

Summary

- Added support for NeuronCore based scheduling to the Neuron Kubernetes Scheduler. Learn more about how to use NeuronCores for finer grain control over container scheduling by following the K8 tutorials documentation in the *containers section*.

15.12.3 Neuron K8 release [2.0.0.0]

Date: 10/10/2022

Summary

- Added support for TRN1 and INF1 EC2 instance types.

15.12.4 Neuron K8 release [1.9.3.0]

Date: 08/02/2022

Summary

- Minor updates.

15.12.5 Neuron K8 release [1.9.2.0]

Date: 05/27/2022

Summary

- Minor updates.

15.12.6 Neuron K8 release [1.9.0.0]

Date: 04/29/2022

Summary

- Minor updates.

15.12.7 Neuron K8 release [1.8.2.0]

Date: 03/25/2022

Summary

- Minor updates.

15.12.8 Neuron K8 release [1.7.7.0]

Date: 01/20/2022

Summary

Minor updates

15.12.9 Neuron K8 release [1.7.3.0]

Date: 10/22/2020

Summary

Support added for use with Neuron Runtime 1.1. More details in the Neuron Runtime release notes at neuron-runtime-release-notes.

15.12.19 [1.1.17.0]

Date: 09/22/2020

Summary

Minor internal enhancements.

15.12.20 [1.0.11000.0]

Date: 08/08/2020

Summary

First release of the Neuron K8 Scheduler extension.

Major New Features

- New scheduler extension is provided to ensure that kubelet is scheduling pods on inf1 with contiguous device ids. Additional details about the new scheduler are provided neuron-k8-scheduler-ext. including instructions on how to apply it.
  - NOTE: The scheduler is only required when using inf1.6xlarge and/or inf1.24xlarge
- With this release the device plugin now requires RBAC permission changes to get/patch NODE/POD objects. Please apply the k8s-neuron-device-plugin-rbac.yml before using the new device plugin.

Resolved Issues

- Scheduler is intended to address https://github.com/aws/aws-neuron-sdk/issues/110

16.1 Compile with Framework API and Deploy on EC2 Inf1

Table of Contents

- *Description*
- *Setup Environment*
  - *1. Launch an Inf1 Instance*
  - *2. Set up a development environment*
    - *Enable PyTorch-Neuron*
    - *Enable TensorFlow-Neuron*
    - *Enable Apache MXNet (Incubating)*
  - *3. Set up Jupyter notebook*

16.1.1 Description

You can use a single inf1 instance as a development environment to compile and deploy Neuron models. In this developer flow, you provision an EC2 inf1 instance using a Deep Learning AMI (DLAMI) and execute the two steps of the development flow in the same instance. The DLAMI comes pre-packaged with the Neuron frameworks, compiler, and required runtimes to complete the flow. Development happens through Jupyter Notebooks or using a secure shell (ssh) connection in terminal. Follow the steps bellow to setup your environment.

Note: **Model compilation can be executed on a non-inf1 instance** for later deployment. Follow the same EC2 Developer Flow Setup using other instance families and leverage Amazon Simple Storage Service (S3) to share the compiled models between different instances.

16.1.2 Setup Environment

1. Launch an Inf1 Instance

- Please follow the instructions at launch an Amazon EC2 Instance to Launch an Inf1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Inf1 instances sizes and pricing see Inf1 web page.
- When choosing an Amazon Machine Image (AMI) make sure to select Deep Learning AMI with Conda Options. Please note that Neuron Conda environments are supported only in Ubuntu 18 DLAMI and Amazon Linux2 DLAMI, Neuron Conda environments are not supported in Amazon Linux DLAMI.
- After launching the instance, follow the instructions in Connect to your instance to connect to the instance

Note: You can also launch the instance from AWS CLI, please see AWS CLI commands to launch inf1 instances.

2. Set up a development environment

Enable PyTorch-Neuron

Important:

For successful installation or update to next releases (Neuron 1.20.0 and newer):

- Uninstall `aws-neuron-dkms` by running: `sudo apt remove aws-neuron-dkms` or `sudo yum remove aws-neuron-dkms`
- Install or upgrade to latest Neuron driver (`aws-neuron-dkms`) by following the "Setup Guide" instructions.

PyTorch 1.9.1

Ubuntu DLAMI

Note: For a successful installation or update, execute each line of the instructions below separately or copy the contents of the code block into a script file and source its contents.

```
# Neuron is pre-installed on Deep Learning AMI (DLAMI), latest DLAMI version may not␣
↪include latest Neuron versions
# To update to latest Neuron version, follow "Update to latest release" instruction on␣
↪Neuron documentation

##########################################################################################
↪#######################
# To install or update to Neuron versions 1.19.1 and newer from previous releases:
# - DO NOT skip 'aws-neuron-dkms' install or upgrade step, you MUST install or upgrade␣
↪to latest Neuron driver
##########################################################################################
↪#######################

# Install OS headers
sudo apt-get install linux-headers-$(uname -r) -y

3. Set up Jupyter notebook

To develop from a Jupyter notebook see setup-jupyter-notebook-steps-troubleshooting

You can also run a Jupyter notebook as a script, first enable the ML framework Conda or Python environment of your choice and see running-jupyter-notebook-as-script for instructions.

This document is relevant for: `Inf1`

Training

This document is relevant for: `Trn1`

16.2 Train your model on EC2

Table of Contents

- *Description*
- *Setup Environment*
  - *1. Launch an Trn1 Instance*
  - *2. Set up a development environment*
    - *Enable PyTorch-Neuron*
  - *3. Set up Jupyter notebook*

16.2.1 Description

You can use a single Trn1 instance as a development environment to compile and train Neuron models. In this developer flow, you provision an EC2 Trn1 instance using a Deep Learning AMI (DLAMI) and execute the two steps of the development flow in the same instance. The DLAMI comes pre-packaged with the Neuron frameworks, compiler, and required runtimes to complete the flow. Development happens through Jupyter Notebooks or using a secure shell (ssh) connection in terminal. Follow the steps bellow to setup your environment.

16.2.2 Setup Environment

1. Launch an Trn1 Instance

- Please follow the instructions at launch an Amazon EC2 Instance to Launch an Trn1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Trn1 instances sizes and pricing see Trn1 web page.
- Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Ubuntu 18 AMI or Amazon Linux 2 AMI, you can also choose Ubuntu 18 or Amazon Linux 2 Deep Learning AMI (DLAMI)
- When launching a Trn1, please adjust your primary EBS volume size to a minimum of 512GB.
- After launching the instance, follow the instructions in Connect to your instance to connect to the instance

Important: AutoScalingGroups is currently not supported on Trn1 and will be added soon.

To launch a Trn1 cluster you can use AWS ParallelCluster, please see example.

Note: Neuron Driver installed on Deep Learning AMI (DLAMI) with Conda does not support Trn1.

If you want to use DLAMI with Conda, please make sure to uninstall `aws-neuron-dkms` and install `aws-neuronx-dkms` before using Neuron on DLAMI with Conda.

2. Set up a development environment

Enable PyTorch-Neuron

PyTorch 1.11.0

Ubuntu 20 AMI

Note:

- Instructions in this page only apply to setting up Neuron components on Linux host running Ubuntu or Amazon Linux AMI.
- When launching a Trn1, please adjust your primary EBS volume size to a minimum of 512GB.

```
# Configure Linux for Neuron repository updates
. /etc/os-release

sudo tee /etc/apt/sources.list.d/neuron.list > /dev/null <<EOF

Amazon EKS

Inference

This document is relevant for: `Inf1`

16.3 Deploy Neuron Container on Elastic Kubernetes Service (EKS)

Table of Contents

- *Description*
- *Setup Environment*
  - *Self-managed Kubernetes*

16.3.1 Description

You can use the Neuron version of the AWS Deep Learning Containers to run inference on Amazon Elastic Kubernetes Service (EKS). In this developer flow, you set up an EKS cluster with Inf1 instances, create a Kubernetes manifest for your inference service and deploy it to your cluster. This developer flow assumes:

1. The model has already been compiled through *Compilation with Framework API on EC2 instance* or through *Compilation with Sagemaker Neo*.
2. You already set up your container to retrieve it from storage.

16.3.2 Setup Environment

1. **Install pre-requisits:** Follow these instruction to install or upgrade the *eksctl* command line utility on your local computer.

   Follow these instruction to install *kubectl* in the same computer. *kubectl* is a command line tool for working with Kubernetes clusters.

2. Follow the instructions in this EKS documentation link to set up AWS Inferentia on your EKS cluster. Using the YML deployment manifest shown in the same link, replace the *image* in the *containers* specification with the one you built using how-to-build-neuron-container above.

   Note: Before deploying your task definition to your EKS cluster, make sure to push the image to ECR. Refer to Pushing a Docker image for more information.

Self-managed Kubernetes

Please refer to tutorial-k8s-env-setup-for-neuron. In *Deploy a TensorFlow Resnet50 model as a Kubernetes service*, the container image referenced in the YML manifest is created using how-to-build-neuron-container.

Training

Note: Amazon EKS support is coming soon.

Amazon ECS

Inference

This document is relevant for: `Inf1`

16.4 Deploy Neuron Container on Elastic Container Service (ECS)

Table of Contents

- *Description*
- *Setup Environment*

16.4.1 Description

You can use the Neuron version of the AWS Deep Learning Containers to run inference on Amazon Elastic Container Service (ECS). In this developer flow, you set up an ECS cluster with inf1 instances, create a task description for your inference service and deploy it to your cluster. This developer flow assumes:

1. The model has already been compiled through *Compilation with Framework API on EC2 instance* or through *Compilation with Sagemaker Neo*.

2. You already set up your container to retrieve it from storage.

16.4.2 Setup Environment

1. **Set up an Amazon ECS cluster:** Follow the instructions on Setting up Amazon ECS for Deep Learning Containers
2. **Define an Inference Task:** Use the instruction on the DLC Inference on ECS Tutorial to define a task and create a service for the appropriate framework.

   When creating tasks for inf1 instances on ECS, be aware of the considerations and requirements listed in Working with inference workloads on Amazon ECS.
3. Use the container image created using how-to-build-neuron-container as the `image` in your task definition.

Note: Before deploying your task definition to your ECS cluster, make sure to push the image to ECR. Refer to Pushing a Docker image for more information.

This document is relevant for: `Inf1`

Training

Note: Amazon ECS supports Trn1.

An example of how to train a model with Neuron using ECS is coming soon.

AWS Sagemaker

Inference

This document is relevant for: `Inf1`

16.5 Compile with Sagemaker Neo and Deploy on Sagemaker Hosting

Table of Contents

- *Description*
- *Setup Environment*

16.5.1 Description

You can use SageMaker Neo to compile models for deployment on SageMaker Hosting using ml.inf1 instances. In this developer flow, you provision a Sagemaker Notebook instance to train, compile and deploy your model using the SageMaker Python SDK. Follow the steps bellow to setup your environment.

16.5.2 Setup Environment

1. Create an Amazon SageMaker Notebook Instance:

   Follow the instructions in Get Started with Notebook Instances

   The Notebook instance created provides the required Python SDK for training, compiling and deploying models with Amazon SageMaker.

2. Compile a model using the Amazon SageMaker SDK:

   Refer to Supported Instances Types and Frameworks for information on the framework versions currently supported by Amazon SageMaker Neo on AWS Inferentia.

   More information about compiling and deploying models with Amazon SageMaker Neo can be found on Use Neo to Compile a Model

This document is relevant for: `Inf1`

16.6 Bring Your Own Neuron Container to Sagemaker Hosting

Table of Contents

- *Description*
- *Setup Environment*

16.6.1 Description

You can use a SageMaker Notebook or an EC2 instance to compile models and build your own containers for deployment on SageMaker Hosting using ml.inf1 instances. In this developer flow, you provision a Sagemaker Notebook or an EC2 instance to train and compile your model to Inferentia. Then you deploy your model to SageMaker Hosting using the SageMaker Python SDK. Follow the steps bellow to setup your environment. Once your environment is set you'll be able to follow the *BYOC HuggingFace pretrained BERT container to Sagemaker Tutorial* .

16.6.2 Setup Environment

1. **Create a Compilation Instance:** If using an **EC2 instance for compilation** you can use an Inf1 instance to compile and test a model. Follow these steps to launch an Inf1 instance:

   - Please follow the instructions at launch an Amazon EC2 Instance to Launch an Inf1 instance, when choosing the instance type at the EC2 console. Please make sure to select the correct instance type. To get more information about Inf1 instances sizes and pricing see Inf1 web page.
   - Select your Amazon Machine Image (AMI) of choice, please note that Neuron support Ubuntu 18 AMI or Amazon Linux 2 AMI, you can also choose Ubuntu 18 or Amazon Linux 2 Deep Learning AMI (DLAMI)
   - After launching the instance, follow the instructions in Connect to your instance to connect to the instance

   If using an **SageMaker Notebook for compilation**, follow the instructions in Get Started with Notebook Instances to provision the environment.

   It is recommended that you start with an ml.c5.4xlarge instance for the compilation. Also, increase the volume size of you SageMaker notebook instance, to accomodate the models and containers built locally. A volume of 10GB is sufficient.

   > **Note:** To compile the model in the SageMaker Notebook instance, you'll need to update the conda environments to include the Neuron Compiler and Neuron Framework Extensions. Follow the installation guide on the section how-to-update-to-latest-Neuron-Conda-Env to update the environments.

2. **Set up the environment to compile a model, build your own container and deploy:** To compile your model on EC2 or SageMaker Notebook, follow the *Set up a development environment* section on the EC2 *Setup Environment* documentation.

   Refer to Adapting Your Own Inference Container documentation for information on how to bring your own containers to SageMaker Hosting.

   Make sure to add the **AmazonEC2ContainerRegistryPowerUser** role to your IAM role ARN, so you're able to build and push containers from your SageMaker Notebook instance.

   Note: The container image can be created using how-to-build-neuron-container.

16.7 Train your model on SageMaker

Table of Contents

- *Description*
- *Setup environment*

16.7.1 Description

SageMaker Training helps you manage cloud computing resources in Amazon EC2, data storage services such as S3, EFS, and FSx, and security management services such as IAM and VPC. SageMaker Training provides you a complete end-to-end experience of training classical ML and state-of-the-art DL models.

You can use SageMaker to train models using Trn1 instances (ml.trn1 instance types). In this developer flow, you provision a SageMaker Notebook instance or SageMaker Studio to train your model using the SageMaker Python SDK.

The Amazon SageMaker Python SDK lets you launch training jobs in just a few lines of code with ease. As shown in the below diagram Amazon SageMaker launches Trn1 instances, copies both data and code onto the instance. It then runs the training script to generate model artifacts. The trained model artifacts are then uploaded to S3 and finally SageMaker will terminate the provisioned instances. In order to speed up the training process for successive runs you can copy the Neuron Persistent Cache to S3 and then copied by future training jobs as they will leverage the cached artifacts. (See Hugging Face fine tuning BERT base model on Amazon SageMaker Tutorial for an example on how to reuse the compiled cache.)

16.7.2 Setup environment

1. Create an Amazon SageMaker Notebook Instance

   Follow the instructions in Get Started with Notebook Instances or Use Amazon SageMaker Studio Notebooks. The Notebook instance provides the required Python SDK for training models with Amazon SageMaker. Please make sure SageMaker Python SDK version is 2.116.0 or later.

2. Train a model using the Amazon SageMaker SDK

   Follow the instructions in Distributed Training with PyTorch Neuron on Trn1 instances. You'll be able to follow the Hugging Face fine tuning BERT base model on Amazon SageMaker Tutorial.

   Note: SageMaker support for EC2 Trn1 instance is currently available only for PyTorch Estimator. HuggingFace Estimator will be available in future release.

AWS ParallelCluster

Training

This document is relevant for: `Trn1`

16.8 Train your model on ParallelCluster

Table of Contents

- *Description*
- *Setup environment*

16.8.1 Description

This document explains how to use AWS ParallelCluster to build HPC compute environment that uses Trn1 compute nodes to run your distributed ML training job. Once the nodes are launched, we will run a training task to confirm that the nodes are working, and use slurm commands to check the job status. In this tutorial, we will use AWS *pcluster* command to run a yaml file in order to generate the cluster. As an example, we are going to launch multiple Trn1.32xl nodes in our cluster.

We are going to set up our ParallelCluster infrastructure as below:

As shown in the figure above, inside a VPC, there are two subnets, a public and a private ones. Head Node resides in the public subnet, while the compute fleet (in this case, trn1 instances) are in the private subnet. A Network Address Translation (NAT) gateway is also needed in order for nodes in the private subnet to connect to clients outside the VPC. In the next section, we are going to describe how to set up all the necessary infrastructure for trn1 ParallelCluster.

16.8.2 Setup environment

1. Install prerequisite infrastructure:

Follow these setup instructions to install VPC and all the necessary components for ParallelCluster.

2. Create and launch ParallelCluster

Follow these creating cluster instructions to launch ParallelCluster in the VPC.

1. Launch training job

Follow these running training instructions to submit a model training script as a slurm job.

This document is relevant for: `Trn1`

Inference

Note: AWS ParallelCluster support is coming soon.

AWS Batch

Inference

Note: AWS Batch supports Inf1.

An example of how to deploy a model with Neuron using Batch is coming soon.

Training

Note: AWS Batch support is coming soon.

CHAPTER

SEVENTEEN

NEURON ARCHITECTURE

The Neuron Archtecture provides insights into Neuron enabled instances system, software and chip capabilities. The EC2 Trn1 and Inf1 instance architecture provides an overview of the EC2 instances powered by the Inferentia and Trainium chips (Neuron Devices), and the corresponding system features like inbox and network connectivity, memory hierarchy, and NeuronCores versions and capabilities. The Neuron model architecture fit provides insights to what is the best match between deep-learning model architectures and the NeuronCore version.

EC2 Inf1 Architecture EC2 Trn1 Architecture AWS NeuronCore Architecture Neuron Model Architecture Fit Guidelines Neuron Glossary

This document is relevant for: `Inf1`

17.1 AWS Inf1 Architecture

In this page, we provide an architectural overview of the AWS Inf1 instances, and the corresponding *Inferentia* NeuronDevices that power them (*Inferentia* devices from here on).

Table of contents

- *Inf1 Architecture*
- *Inferentia Architecture*

17.1.1 Inf1 Architecture

The EC2 Inf1 instance is powered by 16 *Inferentia* devices, and allows customers to choose between four instances sizes:

Instance size	# of Inferentia devices	vCPUs	Host Memory (GiB)	FP16/BF16 TFLOPS	INT8 TOPS	Device Memory (GiB)	Device Memory Bandwidth (GiB/sec)	NeuronLink-v1 device-to-device bandwidth (GiB/sec/device)	EFA bandwidth (Gbps)
Inf1.xlarge	1	4	8	64	128	8	50	N/A	up-to 25
Inf1.2xlarge	1	8	16	64	128	8	50	N/A	up-to 25
Inf1.6xlarge	4	24	48	256	512	32	200	32	25
Inf1.24xlarge	16	96	192	1024	2048	128	800	32	100

Inf1 offers a direct device-to-device interconnect called NeuronLink-v1, which enables co-optimizing latency and throughput via the *Neuron Core Pipeline <neuroncore-pipeline>* technology.

17.1.2 Inferentia Architecture

At the heart of the Inf1 instance are 16 Inferentia devices, as depicted below:

Each Inferentia device consists of:

- **Compute:**
  - 4x *NeuronCore-v1* cores, delivering 128 INT8 TOPS and 64 FP16/BF16 TFLOPS

- **Device Memory:**
  - 8GB of device DRAM memory (for storing parameters and intermediate state), with 50 GB/sec of bandwidth
- **NeuronLink:**
  - Enables co-optimization of latency and throughput via the *Neuron Core Pipeline* technology

This document is relevant for: `Inf1`

This document is relevant for: `Trn1`

17.2 AWS Trn1 Architecture

In this page, we provide an architectural overview of the AWS Trn1 instances, and the corresponding *Trainium* NeuronDevices that power them (Trainium devices from here on).

Table of contents

- *Trn1 Architecture*
- *Trainium Architecture*

17.2.1 Trn1 Architecture

The EC2 Trn1 instance is powered by up to 16 *Trainium* devices, and allows customers to choose between 2 instance sizes:

Instance size	# of Trainium devices	vCPUs	Host Memory (GiB)	FP8/FP16/BF16/TF32 TFLOPS	FP32 TFLOPS	Device Memory (GiB)	Device Memory Bandwidth (GiB/sec)	NeuronLink-v2 device-to-device	EFA bandwidth (Gbps)
Trn1.2xlarge	1	8	32	210	52.5	32	820	N/A	up-to 25
Trn1.32xlarge	16	128	512	3,360	840	512	13,120	Yes	800

The Trn1.2xlarge instance size allows customers to train their models on a single Trainium device, which is useful for small model training, as well as model experimentation. The Trn1.32xlarge instance size comes with a high-bandwidth and low-latency NeuronLink-v2 device-to-device interconnect, which utilizes a 4D-HyperCube topology. This is useful for collective-communication between the Trainium devices during scale-out training, as well as for pooling the memory capacity of all Trainium devices, making it directly addressable from each one of the devices.

In a Trn1 server, the Trainium devices are connected in a 2D Torus topology, as depicted below:

The Trn1 instances are also available in an EC2 UltraCluster, which enables customers to scale Trn1 instances to over 30,000 Trainium devices, and leverage the AWS-designed non-blocking petabit-scale EFA networking infrastructure.

17.2.2 Trainium Architecture

At the heart of the Trn1 instance are Trainium devices, the second generation purpose-built Machine Learning accelerator from AWS. The Trainium device architecture is depicted below:

Each Trainium device consists of:

- **Compute:**
  - 2x *NeuronCore-v2* cores, delivering 420 INT8 TOPS, 210 FP16/BF16/cFP8/TF32 TFLOPS, and 52.5 FP32 TFLOPS.
- **Device Memory:**
  - 32GB of device memory (for storing model state), with 820 GB/sec of bandwidth.
- **Data movement:**
  - 1 TB/sec of DMA bandwidth, with inline memory compression/decompression.
- **NeuronLink:**
  - NeuronLink-v2 for device-to-device interconnect enables efficient scale-out training, as well as memory pooling between the different Trainium devices.
- **Programmability:**
  - Trainium supports dynamic shapes and control flow, via ISA extensions of NeuronCore-v2. In addition, Trainium also allows for user-programmable *rounding mode* (Round Nearest Even Stochastic Rounding), and custom-operators via the deeply embedded GPSIMD Engine.

This document is relevant for: `Inf1`, `Trn1`

17.3 AWS NeuronCore Architecture

In this page, we provide an architectural overview of the AWS NeuronCore architecture across generations.

Table of contents

- *NeuronCore-v1 Architecture*
- *NeuronCore-v2 Architecture*

17.3.1 NeuronCore-v1 Architecture

NeuronCore-v1 is the first generation of the NeuronCore engine, powering the Inferentia NeuronDevices. Each NeuronCore-v1 is a fully-independent heterogenous compute-unit, with 3 main engines (Tensor/Vector/Scalar Engines), and on-chip software-managed SRAM memory, for maximizing data locality (compiler managed, for maximum data locality and optimized data prefetch).

The ScalarEngine is optimized for scalar-computations, in which every element of the output is dependent on one element of the input, e.g. non-linearities like GELU, SIMGOID or EXP. The ScalarEngine is highly parallelized, and can process 512 floating point operations per cycle. It can handle various data-types, including FP16, BF16, FP32, INT8, INT16 and INT32.

The VectorEngine is optimized for vector-computations, in which every element of the output is dependent on multiple input elements. Examples include 'axpy' operations (Z=aX+Y), Layer Normalization, Pooling operations, and many more. The VectorEngine is also highly parallelized, and can perform 256 floating point operations per cycle. It can handle various data-types, including FP16, BF16, FP32, INT8, INT16 and INT32.

The TensorEngine is based on a power-optimized systolic-array which is highly optimized for tensor computations (e.g. GEMM, CONV, Reshape, Transpose), and supports mixed-precision computations (FP16/BF16/INT8 inputs, FP32/INT32 outputs). Each NeuronCore-v1 TensorEngine delivers 16 TFLOPS of FP16/BF16 tensor computations.

17.3.2 NeuronCore-v2 Architecture

NeuronCore-v2 is the second generation of the NeuronCore engine, powering the Trainium NeuronDevices. Each NeuronCore-v2 is a fully-independent heterogenous compute-unit, with 4 main engines (Tensor/Vector/Scalar/GPSIMD Engines), and on-chip software-managed SRAM memory, for maximizing data locality (compiler managed, for maximum data locality and optimized data prefetch).

Just like in NeuronCore-v1, The ScalarEngine is optimized for scalar-computations, in which every element of the output is dependent on one element of the input. The ScalarEngine is highly parallelized, and can perform 1,600 floating point operations per cycle (3x speedup relative to NeuronCore-v1). The NeuronCore-v2 ScalarEngine can handle various data-types, including cFP8, FP16, BF16, TF32, FP32, INT8, INT16 and INT32.

The VectorEngine is optimized for vector-computations, in which every element of the output is dependent on multiple input elements. Examples include 'axpy' operations (Z=aX+Y), Layer Normalization, Pooling operations, and many more. The VectorEngine is also highly parallelized, and can perform 2,500 floating points operations per cycle (10x speedup vs NeuronCore-v1). The NeuronCore-v2 ScalarEngine can handle various data-types, including cFP8, FP16, BF16, TF32, FP32, INT8, INT16 and INT32.

The TensorEngine is based on a power-optimized systolic-array which is highly optimized for tensor computations (e.g. GEMM, CONV, Reshape, Transpose), and supports mixed-precision computations (cFP8 / FP16 / BF16 / TF32 / FP32 / INT8 inputs, FP32 / INT32 outputs). Each NeuronCore-v2 TensorEngine delivers over 100 TFLOPS of FP16/BF16 tensor computations (a 6x speedup from NeuronCore-v1).

NeuronCore-v2 also introduces a new engine, called GPSIMD-Engine. This engine consists of 8 fully programmable 512-bit wide general-purpose processors, which can execute straight-line C-code, and have direct access to the other NeuronCore-v2 engines, as well as the embedded on-chip SRAM memory. With these cores, customers can implement custom-operators and execute them directly on the NeuronCore engines.

NeuronCore-v2 also adds support for control-flow, dynamic-shapes, and programmable *rounding mode* (RNE & Stochastic-rounding).

17.4.1 Introduction

AWS Neuron SDK enables you to train and deploy a wide range of deep learning models on AWS Inferentia and Trainium. Inferentia is the first generation NeuronDevice optimized for inference, and Trainium is the second generation that adds support for model training.

This document describes what types of deep learning model architectures are a good fit for Inferentia and Trainium.

17.4.2 Model Support Overview

AWS Trainium (NeuronCore v2)

Last update - 10/10/2022

Note: Supported means that at least a single model of the model family or the neural-network architecture already enabled.

17.4.3 Natural Language Processing (NLP) Models with Transformers

Encoder models, or autoencoding models with Transformers

Autoencoding models use only the encoder part of the Transformer architecture. Representatives of this family include models like **BERT, distilBERT, XLM-BERT, Roberta, BioBert**, etc. Since the encoding process in these models can be parallelized, you can expect these models to run well both on Inferentia and Trainium.

Trainium

- **Architecture Fit** - Autoencoding models are a good fit for Trainium.
- **Neuron Support** - Neuron SDK supports Autoencoding models training and evaluation on Trainium. Please refer to the Trainium tutorials for more details.

Inferentia

- **Architecture Fit** - Autoencoding models are a good fit for Inferentia.
- **Neuron Support** - Neuron SDK support running Autoencoding models for inference on Inferentia. Please see benchmark results of these models. To get started with NLP models you can refer to Neuron PyTorch, TensorFlow and MXNet NLP tutorials.

Decoder models, or autoregressive models with Transformers

Autoregressive models keep only the decoder part of the Transformer architecture. Representatives of this family include models like **GPT-3, GPT-2**, etc.

Trainium

- **Architecture Fit** - Autoregressive models are a good fit for Trainium.
- **Neuron Support** - Neuron SDK supports Autoregressive models training and evaluation on Trainium. Please refer to the Trainium tutorials for more details.

Inferentia

- **Architecture Fit** - Autoregressive models are not a good fit for Inferentia. Usually the decoder part in these models is the most significant performance bottleneck since it must be executed once per output token, causing frequent access to the memory. Due to this these models typically experience the best performance only when the decoder maximum sequence length is short (e.g., 128).
- **Neuron Support** - Neuron SDK does not support Autoregressive models inference on Inferentia.

Encoder-decoder models, or sequence-to-sequence models with Transformers

Sequence-to-sequence models use both of encoder and decoder of the Transformer architecture. Representatives of this family include models like **T5, Bart, Marian MT**, etc.

Trainium

- **Architecture Fit** - Sequence-to-sequence models are a good fit for Trainium.
- **Neuron Support** - Sequence-to-sequence models are not supported on Trainium as of the latest Neuron release, please track the *Neuron Roadmap* for details.

Inferentia

- **Architecture Fit** - Sequence-to-sequence models are not a good fit for Inferentia. Like decoder models explained above, usually the decoder part in these sequence-to-sequence models is the most significant performance bottleneck since it must be executed once per output token, causing frequent access to the memory. Due to this, even when you enabled the models to run on Inferentia with wrapping the decoder part, these models typically experience the best performance only when the decoder maximum sequence length is short (e.g., 128).
- **Neuron Support** - Neuron SDK does not support sequence-to-sequence models inference on Inferentia out of the box. However, you can run a model with defining wrappers around the encoder and decoder portions of it. For example, please refer to *MarianMT tutorial* on Inferentia for more details.

17.4.4 Computer Vision Models

Convolutional Neural Network (CNN) based models

CNN based models are used for applications in image classification and object detection. Representatives of this family include models like **ResNet, ResNext, VGG, YOLO, SSD**, etc.

Trainium

- **Architecture Fit** - CNN based models are a good fit for Trainium.
- **Neuron Support** - CNN based models are not supported on Trainium as of the latest Neuron release, please track the *Neuron Roadmap* for details.

Inferentia

- **Architecture Fit** - CNN based models are a good fit for Inferentia.
- **Neuron Support** - Neuron SDK supports CNN based models inference on Inferentia. Please see the benchmark results of these models. To get started with these models you can refer to Neuron PyTorch, TensorFlow and MXNet tutorials.

Region-based CNN (R-CNN) models

Region-based CNNs (R-CNNs) models are commonly used for object detection and image segmentation tasks. Popular variants of the the R-CNN model include R-CNN, Fast R-CNN, Faster R-CNN, and Mask R-CNN.

Trainium

- **Architecture Fit** - R-CNN models are a good fit for Trainium.
- **Neuron Support** - R-CNN models are not supported on Trainium as of the latest Neuron release, please track the *Neuron Roadmap* for details.

Inferentia

- **Architecture Fit** - R-CNN models can have a few limitations and considerations on Inferentia: **RoI Align operators**: At this time, RoI Align operators typically cannot run efficiently on NeuronCore v1. As a result, RoI Align operators are mapped directly to CPU during compilation. R-CNN models that predict a low number of bounding boxes (<100) experience the best performance on Inferentia. **Large ResNet backbone**: R-CNNs that have a large ResNet backbone (such as ResNet-50 or ResNet-101) experience the greatest performance improvement on Inferentia because a larger portion of the R-CNN compute is accelerated.
- **Neuron Support** - Torch models must be traceable using `torch.jit.trace()` for compilation on Inferentia. Most Detectron2-based R-CNNs are not jit traceable by default, so they cannot readily be compiled for optimized inference on Inferentia. The *Running R-CNNs on Inf1* application note demonstrates how to compile and improve the performance of R-CNN models on Inferentia. It also provides an end-to-end example of running a Detectron2 R-CNN on Inferentia.

17.4.5 Models with Long Short-Term Memory (LSTM) networks

LSTMs use an internal state to process sequential data. LSTMs are commonly used to model temporal sequences of data in language processing and computer vision applications.

Trainium

- **Architecture Fit** - Models with LSTM networks are a good fit for Trainium.
- **Neuron Support** - Models with LSTM networks are not supported on Trainium as of the latest Neuron release. Please track the *Neuron Roadmap* for details.

Inferentia

- **Architecture Fit** - Models with LSTM cells are a good fit for Inferentia.
- **Neuron Support** - Models with LSTM networks are supported on Inferentia, please see *Developer Guide - PyTorch Neuron (torch-neuron) LSTM Support*.

17.4.6 Diffusion Models

Trainium

- **Architecture Fit** - Diffusion models are a good fit for Trainium.
- **Neuron Support** - Diffusion models are not supported on Trainium as of the latest Neuron release. Please track the *Neuron Roadmap* for details.

Inferentia

- **Architecture Fit** - Diffusion models are a good fit for Inferentia.
- **Neuron Support** - Diffusion models are not supported on Inferentia as of the latest Neuron release. Please track the *Neuron Roadmap* for details.

17.4.7 Known Issues on Inferentia (NeuronCore v1)

Support of large models (impacts *torch-neuron* and *tensorflow-neuron* (TF1.x))

During compilation on Inferentia (NeuronCore v1), `torch-neuron` and `tensorflow-neuron (TF1.x)` export a protobuf that contains the model's graph structure and weights. This causes an issue when the total size of the model's weights exceeds the 2GB limitation of protobufs. As a result, customers who want to run large models such as **RegNet**, **Stable Diffusion**, and **t5-11b** might run into protobuf errors during compilation.

This is a known issue related to the compilation process, not a hardware-dependent issue. Allowing large models like this to be compiled for inference on Inferentia (NeuronCore v1) is a feature that we intend to address in a future release. Please track the *Neuron Roadmap* for details.

Note: Neuron release 2.5.0 added Experimental support for tracing models larger than 2GB *in `tensorflow-neuron (TF2.x)`*, please see `extract-weights` flag in *TensorFlow 2.x (tensorflow-neuron) Tracing API*

17.5 Neuron Glossary

Table of contents

- *Terms*
  - *Neuron Devices (Accelerated Machine Learning chips)*
  - *Neuron powered Instances*
  - *NeuronCore terms*
- *Abbreviations*

17.5.1 Terms

Neuron Devices (Accelerated Machine Learning chips)

Term	Description
Inferentia	AWS first generation accelerated machine learning chip supporting inference only
Trainium	AWS second generation accelerated machine learning chip supporting training and inference
Neuron Device	Accelerated machine learning chip (e.g. Inferentia or Trainium)

Neuron powered Instances

Term	Description
Inf1	Inferentia powered accelerated compute EC2 instance
Trn1	Trainium powered accelerated compute EC2 instance

NeuronCore terms

Term	Description
NeuronCore	The machine learning compute cores within Inferentia/Trainium
NeuronCore-v1	Neuron Core withing Inferentia
NeuronCore-v2	Neuron Core withing Trainium
Tensor Engine	2D systolic array (within the NeuronCore), used for matrix computations
Scalar Engine	A scalar-engine within each NeuronCore, which can accelerate element-wise operations (e.g. GELU, ReLU, reciprocal, etc)
Vector Engine	A vector-engine with each NeuronCore, which can accelerate spatial operations (e.g. layerNorm, TopK, pooling, etc)
GPSIMD Engine	Embedded General Purpose SIMD cores, within each NeuronCore, to accelerate custom-operators
Sync Engine	The SP engine, which is integrated inside NeuronCore. Used for synchronization and DMA triggering.
Collective Communication Engine	Dedicated engine for collective communication, allows for overlapping computation and communication
NeuronLink	Interconnect between NeuronCores
NeuronLink-v1	Interconnect between NeuronCores in Inferentia device
NeuronLink-v2	Interconnect between NeuronCores in Trainium device

17.5.2 Abbreviations

Abbreviation	Description
NC	Neuron Core
NeuronCore	Neuron Core
ND	Neuron Device
NeuronDevice	Neuron Device
TensEng	Tensor Engine
ScalEng	Scalar Engine
VecEng	Vector Engine
SyncEng	Sync Engine
CCE	Collective Communication Engine
FP32	Float32
TF32	TensorFloat32
FP16	Float16
BF16	Bfloat16
cFP8	Configurable Float8
RNE	Round Nearest Even
SR	Stochastic Rounding
CustomOps	Custom Operators
RT	Neuron Runtime
DP	Data Parallel
DPr	Data Parallel degree
TP	Tensor Parallel
TPr	Tensor Parallel degree

18.1 Data Types

Table of contents

- *Introduction*
- *NeuronCore v1 Data Types*
  - *Neuron Data-Types*
- *NeuronCore v2 Data Types*
  - *Model Type Conversion*
  - *NeuronCore v2 Rounding Modes*

18.1.1 Introduction

Inferentia and Trainium NeuronDevices include different NeuronCore versions, which support differnt data-types. This section describes what data-types are supported in each NeuronCore version, for details about NeuronCore versions see neuron_hw_arch.

18.1.2 NeuronCore v1 Data Types

Neuron Data-Types

Neuron enables developers to choose from multiple data-types. The supported data-types are FP32, FP16, and BF16. Developers can train their models on their platform of choice (e.g. EC2 P3 instances), and then easily move their trained models to EC2 Inf1 for execution.

FP16/BF16 models

Models natively trained in FP16/BF16 will be executed in their trained data-types. This is a straightforward migration from the training platform to Inf1.

FP32 models

Neuron SDK supports **automatic model conversion** from FP32 to BF16 by default. This capability allows developers to train their models using FP32 format for the highest accuracy, and achieve performance benefits without having to worry about low-precision training (e.g. no need for loss-scaling during training). ML models are typically robust to FP32 to BF16 conversion, with minimal to no impact on accuracy. The conversion accuracy is model dependent; therefore, users are encouraged to benchmark the accuracy of the auto-converted model against the original FP32 trained model.

When the compiler is supplied with an unmodified FP32 model input it will automatically compile the model to run as BF16 on Inferentia. During inference the FP32 input data will be auto-converted internally by Inferentia to BF16 and the output will be converted back to FP32 data-type. For explicit FP16 inferencing, either use an FP16 trained model, or use an external tool (like AMP) to make the explicit conversions.

18.1.3 NeuronCore v2 Data Types

The NeuronCore v2 supports the following data types:

- 32 and 16-bit Floating Point (FP32 / FP16)
- TensorFloat-32 (TF32)
- Brain Floating Point (BFloat16)
- Unsigned 8-bit integer (UINT8)

Note: Neuron Compiler support for UINT8 is planned for a future Neuron SDK release. See Neuron Compiler: Enable Neuron INT8 support for details.

The layout for these is as follows:

Model Type Conversion

The Neuron SDK supports automatic model conversion from FP32 to BF16 by default. This capability allows developers to train their models using FP32 format for the highest accuracy, and then achieve run-time performance benefits without having to worry about low-precision training (e.g. no need for loss-scaling during training). ML models are typically robust to FP32 to BF16 conversion, with minimal to no impact on accuracy. Since conversion accuracy is model dependent, users are encouraged to benchmark the accuracy of the auto-converted model against the original FP32 trained model.

See *Mixed Precision and Performance-accuracy Tuning for Training* for more details on supported data types and their properties.

The Neuron compiler offers the `--auto-cast` and `--auto-cast-type` options to specify automatic casting of FP32 tensors to other data types to address performance and accuracy tradeoffs. See the *Neuron Compiler CLI Reference Guide* for a description of these options.

NeuronCore v2 Rounding Modes

Because floating point values are represented by a finite number of bits, they cannot represent all real numbers accurately. Floating point calculations that exceed their defined data type size are rounded. The NeuronCore v2 performs a Round-to-Nearest (RNE) algorithm with ties to Even by default. It also provides a new Stochastic Rounding mode. When Stochastic Rounding is enabled, the hardware will round the floating point value up or down using a proportional probability. This could lead to improved model convergence. Use the environment variable NEURON_RT_STOCHASTIC_ROUNDING_EN to select a rounding mode.

This document is relevant for: `Inf1`, `Trn1`

This document is relevant for: `Trn1`

18.2 Neuron Rounding Modes

Table of contents

- *Round Nearest, ties to Even (RNE)*
- *Stochastic Rounding (SR)*
- *Quick Tests*

18.2.1 Round Nearest, ties to Even (RNE)

When the exact result of a floating point operation cannot be exactly represented as a floating point value, it must be rounded. The IEEE 754-2008 standard defines the default rounding mode to be 'Round Nearest, ties to Even' (RNE for short). Under this scheme, numbers are rounded to the nearest representable value, and in case of a 'tie' (i.e. the number is exactly between the two nearest representable values) numbers will be rounded to the nearest even number.

All NeuronCore generations support the RNE rounding scheme, which is the most commonly used rounding scheme for Machine Learning workloads. Below is an illustration of the RNE rounding scheme:

18.2.2 Stochastic Rounding (SR)

One downside of the RNE rounding scheme (and other rounding schemes described in the IEEE 754-2008 standard), is that when adding floating point values of significantly different magnitudes, rounding can squash small values and prevent them from accumulating over time.

To improve this, starting from the second generation of the NeuronCore (NeuronCore-v2), customers can choose between the RNE rounding scheme described above, and a second rounding scheme called 'Stochastic Rounding' (SR for short). Stochastic rounding prevents the computation precision-loss described above, by performing the rounding operations in a probabilistic manner, according to the relative distance from the two nearest representable values, as illustrated below:

By performing the rounding in a probabilistic manner, this scheme allows for small increments to accumulate over time, even when added to numbers of significantly higher magnitude, which leads to more precise results when performing large floating point computations (as done for machine learning).

18.2.3 Quick Tests

As an example, we examine the code-snippet below:

```
import torch
import torch_xla
import torch_xla.core.xla_model as xm
device = xm.xla_device()

a = torch.tensor(1024.0).half().to(device)

for i in range(2048) :
   a = (a + 0.5)
   xm.mark_step()

print(a)
```

This code shows that rounding can significantly impact the calculation's precision over time. To use standard RNE rounding, use the environment variable `NEURON_RT_STOCHASTIC_ROUNDING_EN=0`. To enable stochastic rounding, use the environment variable `NEURON_RT_STOCHASTIC_ROUNDING_EN=1`.

NOTE: Stochastic rounding mode is enabled by default in PyTorch-Neuron when XLA_USE_BF16=1.

The first test continues to show 1024 due to RNE rounding after each addition, and the second test shows result that is mostly in line with expectation.

```
$ NEURON_RT_STOCHASTIC_ROUNDING_EN=0 python3 rounding_mode_test.py

tensor(1024., device='xla:1', dtype=torch.float16)

$ NEURON_RT_STOCHASTIC_ROUNDING_EN=1 python3 rounding_mode_test.py

tensor(2056., device='xla:1', dtype=torch.float16)
```

This document is relevant for: `Trn1`

This document is relevant for: `Inf1`

18.3 Neuron Batching

Note: This document is being updated to reflect *NeuronCore-v2 Architecture* and training support.

Batching refers to the process of grouping multiple inference requests together and processing them as a group. Batching is typically used as an optimization for throughput at the expense of higher latency. Batching is usually implemented on a layer-by-layer basis, which allows for each set of weights in a given layer to be reused for each inference in the batch before needing to retrieve additional new weights. This enables Neuron to better amortize the cost of reading weights from the external memory (i.e. read weights from the memory once, and use them in multiple calculations), and thus improve the overall hardware efficiency.

The concept of batched inference is illustrated in the example below, with a single NeuronCore performing batched computation of a 3 layer neural network with a batch-size of 4. The NeuronCore reads weights from the external memory, and then performs the corresponding computations for all 4 inference-requests, before reading the next set of weights, thus better amortizing the cost of reading the weights from the memory.

Neuron uses an ahead-of-time compiler, so to enable batching in Neuron, a model should be explicitly compiled for a target batch-size by setting the input-tensor batch dimension accordingly. Users are encouraged to evaluate multiple batch sizes, in order to determine the optimal latency/throughput deployment-point (which is model/application dependent).

During inference, dynamic batching can be used to process a larger client-side inference batch-size, and allow the framework to automatically break up the user-batch into smaller batch sizes, to match the compiled batch-size. This technique increases the achievable throughput by hiding the framework-to-neuron overhead, and amortizing it over a larger batch size. To enable dynamic batching in TensorFlow, user would set the argument `dynamic_batch_size=True` during call to `tfn.saved_model.compile` method.

For example, the TensorFlow code snippet below enables batching, with dynamic-batching and a batch-size of N=4 when compiling a model to Inferentia target:

```
import numpy as np
import tensorflow.neuron as tfn

# To change the batch size, change the first dimension in example_input
batch_sz = 4
example_input = np.zeros([batch_sz, 224, 224, 3], dtype='float16')

# Note: You can add custom compilation flags such as for mixed precision
# here. None are needed for this model.
compiler_args = []

tfn.saved_model.compile("rn50_fp16",
                        "rn50_fp16_compiled/1",
                        model_feed_dict={'input_1:0': example_input },
                        dynamic_batch_size=True,
                        compiler_args=compiler_args)
```

The following TensorFlow code snippet shows that the model can accept inference requests with arbitrary batch size:

```
import tensorflow as tf
import tensorflow.neuron as tfn

predictor = tf.contrib.predictor.from_saved_model("rn50_fp16_compiled/1")
rt_batch_sz_list = [1, 4, 7, 8, 1024]
for rt_batch_sz in rt_batch_sz_list:
    example_input = np.zeros([rt_batch_sz, 224, 224, 3], dtype='float16')
    model_feed_dict = {'input_1:0': example_input}
    result = predictor(model_feed_dict)
```

Note: Depending on the neural network size, Neuron will have a maximum batch size that works optimally on Inferentia. If an unsupported batch size is used, an internal compiler error message will be displayed. A simple way to explore optimal batch size for your specific model is to increment the batch size from 1 upward, one at a time, and test application performance.

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

18.4 NeuronCore Pipeline

The Neuron software feature referred to as a NeuronCore Pipeline refers to the process of sharding a compute-graph across multiple NeuronCores, caching the model parameters in each core's on-chip memory (cache), and then streaming inference requests across the cores in a pipelined manner. Based on the number of NeuronCores selected, the model might get seamlessly sharded across up-to 16 Inferentia devices (i.e. 64 NeuronCores). This enables users to optimize for both throughput and latency, as it enables the NeuronCores to process neural-networks with locally cached data and avoid the cost of accessing external memory.

One benefit to this approach is that NeuronCore Pipeline can typically hit maximal hardware efficiency without the need for batching (e.g. BERT, ResNet50).

For maximal performance, users should choose an instance-size that can cache the entire model by using sufficient NeuronCores. Inf1 instance types have different number of Inferentia devices, each of which has 4 NeuronCores, as shown here https://aws.amazon.com/ec2/instance-types/inf1/

To enable the NeuronCore Pipeline optimization, the compiler should be invoked with the following flags: `--neuroncore-pipeline-cores N`. The number of NeuronCores is typically chosen to be the minimal number that can fit the entire model, which is currently done through a trial-and-error process (compiling to different number of cores and looking for compilation success/failure message). This process will be automated in the future. A simple formula to help define the number of NeuronCores that may be an appropriate choice is

```
neuroncore-pipeline-cores = 4 * round( number-of-weights-in-model/(2 * 10^7) )
```

This allocates a set of NeuronCores based on the size of the given model's weights and normalizes to multiples of 4 so it uses full Inferentias.

The code snippet below shows how to compile a model with NeuronCore Pipeline for 16 NeuronCores (instance size inf1.6xlarge).

```
import numpy as np
import tensorflow.neuron as tfn

example_input = np.zeros([1,224,224,3], dtype='float16')
tfn.saved_model.compile("rn50_fp16",
                        "rn50_fp16_compiled/1",
                        model_feed_dict={'input_1:0' : example_input },
                        compiler_args = ['--neuroncore-pipeline-cores', '16'])
```

This document is relevant for: `Trn1`

18.5 Neuron Persistent Cache

PyTorch Neuron (`torch-neuronx`) uses `torch-xla`, and `torch-xla` operates in lazy mode. In other words, every operation in training script is recorded in a graph. The graph is executed only when the results are requested by the user when they use `print` or `xm.mark_step`. Requesting results tells `torch-xla` that the recorded graph needs to be executed.

Before executing the graph, `torch-xla` would call Neuron Compiler (`neuronx-cc`) to compile the graph into Neuron specific graph. Then the graph is executed on the *NeuronCore/s*. Compiling the graph involves running optimizations that can make use of the *NeuronCore/s* efficiently. Running these optimizations can be expensive and can result in long compile times. To save the users from compiling these graphs at every iteration, `torch-xla` maintains an in-memory cache called Just in Time (JIT) cache. When the user re-runs the same graph (eg. 2nd iteration of the training run), torch-xla would check in this JIT cache and re-use the cached compilation result, thereby avoiding the wait times.

Since the JIT cache is an in-memory cache, it needs to be constructed every time the training script is run. Hence, if the user re-runs the training script, a new JIT cache is created. This causes a compilation for the first training graph. To avoid such compilations across training runs, PyTorch Neuron (`torch-neuronx`) has built an on-disk `Neuron Persistent Cache`. Since this cache is on-disk, its persistent across training runs. So now, when a graph is compiled for the fist time, the compilation result is saved in `Neuron Persistent Cache`. When the user re-runs the training script, since the JIT cache is not ready, it would send the graph for compilation. PyTorch Neuron (`torch-neuronx`) would then check if the compiled result is present in the `Neuron Persistent Cache`, if yes, it would return with the compiled result. This on-disk cache thereby avoids compilations across training runs. This cache is enabled by default and the default cache directory is `/var/tmp/neuron-compile-cache`.

Look at the diagram below on the end to end flow:

As seen from the diagram, the operations are recorded in a graph in lazy mode and only when a mark_step is hit, the graph is executed. Before execution, the graph passes through two caches to check if we have compiled the graph sometime in the past. If yes, we reuse the compilation result and execute with it. This avoid duplicate compilations. One thing to note, both JIT cache and Neuron Cache are complementary to each other. JIT cache prevents duplicate compilation within a run and Neuron Cache prevents duplicate compilations across training runs. For example, within a training script, we have a training loop that iterates through the dataset. The first iteration would trace a unique graph and the following iteration would trace a graph that is similar to the first one. In this case, the subsequent iterations would hit the JIT cache and reuse the result. However, to save users from compiling for the first iteration graph, `Neuron Persistent Cache` would be used. In this case, the very first time when the script is run, the `Neuron Persistent Cache` would be updated. Going forward when we re-run the training script, compilation results from

`Neuron Persistent Cache` would be used.

To better understand how `Neuron Persistent Cache` works, consider the example below:

```
import torch
import torch_xla
import torch_xla.core.xla_model as xm
device = xm.xla_device()
t1 = torch.randn(3, 3).to(device)
t2 = t1 / 0.5
x = t2.cpu()
```

Running the above example produces the following logs:

```
2022-07-17 17:59:53.000541: INFO ||NCC_WRAPPER||: No candidate found under /var/tmp/
↪neuron-compile-cache/USER_neuroncc-2.0.0.48+e5fcdf753/MODULE_8742523875190354238.
2022-07-17 17:59:53.000541: INFO ||NCC_WRAPPER||: Cache dir for the neff: /var/tmp/

.
Compiler status PASS
2022-07-17 18:00:01.000117: INFO ||NCC_WRAPPER||: Exiting with a successfully compiled␣
↪graph
```

Re-running the above script would fetch the graph from the neuron cache and you would see logs as follows:

```
2022-07-17 18:05:37.000179: INFO ||NCC_WRAPPER||: Using a cached neff at /var/tmp/neuron-
↪compile-cache/USER_neuroncc-2.0.0.48+e5fcdf753/MODULE_8742523875190354238/MODULE_0_
↪SyncTensorsGraph.6_8742523875190354238_ip-172-31-43-112.ec2.internal-e7aed083-14217-
↪5e404023e468c/d3d4b823-0872-418e-bf85-390dbce2bec3/MODULE_0_SyncTensorsGraph.6_
↪8742523875190354238_ip-172-31-43-112.ec2.internal-e7aed083-14217-5e404023e468c.neff.␣
↪Exiting with a successfully compiled graph
```

As you can see, the next run picks the compiled graph from cache, thereby saving the compilation time. The cache uses hash of the Neuron compiler flags and XLA graph as the key. If the Neuron compiler version or XLA graph changes, you will see recompilation. Examples of changes that would cause XLA graph change include:

- Model type and size
- Batch size
- Optimizer and optimizer hyperparameters
- Location of xm.mark_step()

All compilation results are saved in the cache. To disable the cache, you can pass `--no_cache` option via NEURON_CC_FLAGS:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --no_cache'
```

To change the cache's root directory, pass `--cache_dir=<root dir>` option via NEURON_CC_FLAGS (the actual cache directory will be in `<root dir>/neuron-compile-cache`):

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --cache_dir=
↪<root dir>'
```

Stale cached compiled graphs (NEFFs) are deleted from the cache whenever the size of cache is above default cache size of 100GB . The deletion order is based on least-recently-used first. To change the cache size, pass `--cache_size=SIZE_IN_BYTES`. For example, to change the cache size to 16 MB:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --cache_
↪size=16777216'
```

A cache entry considered stale if the last used time is older than a time-to-live value, currently default to 30 days. If the last used time is earlier than the time-to-live value, then it is not deleted even if cache size exceeds cache size limit. To change cache time-to-live, set the option `--cache_ttl` to the number of days desired:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --cache_ttl=60'
```

You can change the verbose level of the compiler by adding `log_level` to either `WARNING`, `INFO` or `ERROR`. This can be done as follows:

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --log_
↪level=INFO'
```

Note: All compilation results are saved in the cache. In other words even if there is a failed compilation, its result would be saved in the cache. If you want to retry a failed compilation, you can do so by using `--retry_failed_compilation`.

```
os.environ['NEURON_CC_FLAGS'] = os.environ.get('NEURON_CC_FLAGS', '') + ' --retry_failed_
↪compilation'
```

Setting the above flag, would retry all the failed compilations and save fresh results in the cache.

This document is relevant for: `Trn1`

18.6 Collective Communication

Collective Communications is an integral component of distributed ML training. Multiple training nodes exchange information during ML training via Collective Communication operators such as all-reduce. Neuron provides hardware support for the execution of Collective Communication with the Neuron SDK responsible for the hardware configuration and for the execution orchestration. Neuron provides the following Collective Communication operators:

- all-reduce
- all-gather
- reduce-scatter

Neuron also provides the following peer to peer operators:

- send
- receive

Support for additional Collective Communication operators might be added in future releases. Neuron devices are connected via NeuronLinks within a single instance and EFA links between instances. All NeuronLinks transfer the data directly between Neuron device and between Neuron devices and EFA devices bypassing the host to achieve high bandwidth and low latency.

On a single instance Neuron devices are connected in a 2D torus topology supporting Collective Communication operators in sets of 2, 8 and 32 ranks. Other set sizes might be supported in future releases. A single instance topology can be further extended across multiple instances using EFA NeuronLinks.

Trn1.32xl 2D torus topology

For example an 8x4 topology on a single instance, such as 8 rank tensor parallel and 4 ranks data parallel can be extended across multiple instances creating a large tensor/data parallel training cluster.

Collective Communication support on Neuron requires installation of 3 separate packages:

- `aws-neuronx-runtime-lib` - supports execution on Neuron, not specific to Collective Communication and is always required
- `aws-neuronx-collectives` - supports Collective Communication execution on a single instance and on multiple instances.
- `efa_installer` - low level libraries and drivers to support Collective Communication execution over EFA, required to support Collective Communication on multiple instances.

ML models need to be compiled by the Neuron compiler before they can be executed on Neuron devices. The result of the compilation is a binary object containing computational instruction and data movement instructions.

Any Collective Communication operators encountered during compilation are converted to the place holder instructions to be filled by the runtime/collectives libraries during load and execution. This approach allows Neuron compiler to be unaware of the specific physical topology connecting Neuron devices. Once a compiled mode is placed on Neuron devices the runtime/collectives libraries generate the appropriate data movement instructions based on the placement.

For example, a different set of instructions is generated when the next rank is connected via NeuronLinks or via EFA. Neuron executes Collective Communication operators using dedicated hardware that is not shared with computational resources. That allows Neuron to execute compute and communication in parallel. For example Neuron can all-reduce gradients of one layer while the gradients for another layer are computed. Overlapping compute and communication can result is lower latency and higher performance.

NEURON APPLICATION NOTES

Neuron 2.x

This document is relevant for: `Inf1`, `Trn1`

19.1 Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)

Neuron release 2.3 is the first release of Neuron 2.x, and which enables GA of the new EC2 Trn1 instances. Neuron release 2.3 extends latest release of Neuron 1.x (Neuron 1.19.2) to add support for deep-learning training on the AWS Trainium chips.

Starting with Neuron release 2.3, developers can run deep learning training workloads on Trn1 instances to save training costs by up to 50% over equivalent GPU-based EC2 instances, while getting the highest training performance in AWS cloud for popular NLP models. Neuron 2.x introduces the new capabilities and major architectural updates to support training neural-networks with the Trn1 instances.

In addition, starting with this release, Neuron introduces new packages, renames several packages, and updates Neuron installation and update instructions. This release also ends the support for Neuron Runtime 1.x.

  - *Application unexpected behavior when downgrading to releases before* Neuron 1.6.0 *(from* Neuron 1.16.0 *or newer)*
  - *Neuron Core is in use*
- *Frequently Asked Questions (FAQ)*
  - *Do I need to recompile my model to run it with Neuron Runtime 2.x (*`libnrt.so`*)?*
  - *Do I need to change my application launch command?*
  - *Can* `libnrt.so` *and* `neuron-rtd` *co-exist in the same environment?*
  - *Are there Neuron framework versions that will not support Neuron Runtime 2.x (*`libnrt.so`*)?*

19.2.1 What are we changing?

Starting with *Neuron 1.16.0* release, *Neuron Runtime 1.x* (`neuron-rtd`) is entering maintenance mode and is replaced by *Neuron Runtime 2.x*, a shared library named (`libnrt.so`). For more information on Runtime 1.x see maintenance_rtd.

Upgrading to `libnrt.so` simplifies Neuron installation and upgrade process, introduces new capabilities for allocating NeuronCores to applications, streamlines container creation, and deprecates tools that are no longer needed.

This document describes the capabilities of *Neuron Runtime 2.x* in detail, provides information needed for successful installation and upgrade, and provides information needed for successful upgrade of Neuron applications using *Neuron Runtime 1.x* (included in releases before *Neuron 1.16.0*) to *Neuron Runtime 2.x* (included in releases *Neuron 1.16.0* or newer).

19.2.2 Why are we making this change?

Before *Neuron 1.16.0*, Neuron Runtime was delivered as a daemon (`neuron-rtd`), and communicated with Neuron framework extensions through a `gRPC` interface. `neuron-rtd` was packaged as an `rpm` or `debian` package (`aws-neuron-runtime`) and required a separate installation step.

Starting with *Neuron 1.16.0*, *Neuron Runtime 2.x* is delivered as a shared library (`libnrt.so`) and is directly linked to Neuron framework extensions. `libnrt.so` is packaged and installed as part of Neuron framework extensions (e.g. TensorFlow Neuron, PyTorch Neuron or MXNet Neuron), and does not require a separate installation step. Installing Neuron Runtime as part of the Neuron framework extensions simplifies installation and improves the user experience. In addition, since `libnrt.so` is directly linked to Neuron framework extensions, it enables faster communication between the Neuron Runtime and Neuron Frameworks by eliminating the `gRPC` interface overhead.

For more information please see *How will this change affect the Neuron SDK?* and *Migrate your application to Neuron Runtime 2.x (libnrt.so)*.

19.2.3 How will this change affect the Neuron SDK?

Neuron Driver

You need to use latest Neuron Driver. For successful installation and upgrade to *Neuron 1.16.0* or newer, you must install or upgrade to Neuron Driver (`aws-neuron-dkms`) *version 2.1.5.0* or newer. Neuron applications using *Neuron 1.16.0* will fail if they do not detect *Neuron Driver version 2.1.5.0* or newer. For installation and upgrade instructions see install-guide-index.

Important: Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

To see details of Neuron component versions please see neuron-release-content.

Important:

For successful installation or update to Neuron 1.16.0 and newer from previous releases:

- Stop Neuron Runtime 1.x daemon (`neuron-rtd`) by running: `sudo systemctl stop neuron-rtd`
- Uninstall `neuron-rtd` by running: `sudo apt remove aws-neuron-runtime` or `sudo yum remove aws-neuron-runtime`
- Install or upgrade to latest Neuron Driver (`aws-neuron-dkms`) by following the install-guide-index instructions.
- Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

Neuron Runtime

- Installation Starting from *Neuron 1.16.0*, Neuron releases will no longer include the `aws-neuron-runtime packages`, and the Neuron Runtime will be part of the Neuron framework extension of choice (TensorFlow Neuron, PyTorch Neuron or MXNet Neuron). Installing any Neuron framework package will install the Neuron Runtime library (`libnrt.so`).
  - For installation and upgrade instructions see install-guide-index.
- **Configuring *Neuron Runtime*** Before *Neuron 1.16.0*, configuring *Neuron Runtime 1.x* was performed through configuration files (e.g. /opt/aws/neuron/config/neuron-rtd.config). Starting from *Neuron 1.16.0*, configuring *Neuron Runtime 2.x* can be done through environment variables, see *Neuron Runtime Configuration* for details.
- **Starting and Stopping *Neuron Runtime*** Before introducing `libnrt.so`, `neuron-rtd` ran as a daemon that communicated through a `gRPC` interface. Whenever `neuron-rtd` took ownership of a Neuron device, it continued owning that device until it was stopped. This created the need to stop `neuron-rtd` in certain cases. With the introduction of `libnrt.so`, stopping and starting the *Neuron Runtime* is no longer needed as it runs inside the context of the application. With *Neuron Runtime 2.x*, the act of starting and stopping a Neuron application will cause `libnrt.so` to automatically claim or release the ownership of the required Neuron devices.
- **NeuronCore Groups (NCG) deprecation** Before the introduction of *Neuron Runtime 2.x*, NeuronCore Group (NCG) has been used to define an execution group of one or more NeuronCores where models can be loaded and executed. It also provided separation between processes.

  With the introduction of *Neuron Runtime 2.x*, the strict separation of NeuronCores into groups is no longer needed and NeuronCore Groups (NCG) is deprecated. see eol-ncg for more information.
- **Running multiple *Neuron Runtimes*** Before the introduction of `libnrt.so`, you needed to run multiple `neuron-rtd` daemons to allocate Neuron devices for each `neuron-rtd` using configuration files. After the introduction of `libnrt.so`, you will no longer need to run multiple `neuron-rtd` daemons to allocate Neuron devices to specific Neuron application . With `libnrt.so` allocation of NeuronCores (Neuron device include multiple NeuronCores) to a particular application is done by using `NEURON_RT_VISIBLE_CORES` or `NEURON_RT_NUM_CORES` environment variables, for example:

  ```
  NEURON_RT_VISIBLE_CORES=0-3 myapp1.py
  NEURON_RT_VISIBLE_CORES=4-11 myapp2.py
  ```

  Or

  ```
  NEURON_RT_NUM_CORES=3 myapp1.py &
  NEURON_RT_NUM_CORES=4 myapp2.py &
  ```

  See *Neuron Runtime Configuration* for details.
- **Logging** Similar to *Neuron Runtime 1.x*, *Neuron Runtime 2.x* logs to syslog (verbose logging). To make debugging easier, *Neuron Runtime 2.x* also logs to the console (error-only logging). Refer to *Neuron Runtime Configuration* to see how to increase or decrease logging verbosity.
- **Multi-process access to NeuronCores** With the introduction of `libnrt.so`, it's no longer possible to load models on the same NeuronCore from multiple processes. Access to the same NeuronCore should be done from the same process. Instead you can load models on the same NeuronCore using multiple threads from the same process.

  Note: For optimal performance of multi-model execution, each NeuronCore should execute single model.

- **Neuron Runtime architecture** *Neuron Runtime 2.x* is delivered as a shared library (`libnrt.so`) and is directly linked to Neuron framework extensions. `libnrt.so` is packaged and installed as part of Neuron framework extensions (e.g. TensorFlow Neuron, PyTorch Neuron or MXNet Neuron), and does not require a separate installation step. Installing Neuron Runtime as part of the Neuron framework extensions simplifies installation and improves the user experience. In addition, since `libnrt.so` is directly linked to Neuron framework extensions, it enables faster communication between the Neuron Runtime and Neuron Frameworks by eliminating the `gRPC` interface overhead.

Neuron framework extensions

Starting from *Neuron 1.16.0*, Neuron framework extensions (TensorFlow Neuron, PyTorch Neuron or MXNet Neuron) will be packaged together with `libnrt.so`. It is required to install the `aws-neuron-dkms` Driver version 2.1.5.0 or newer for proper operation. The `neuron-rtd` daemon that was installed in previous releases no longer works starting with Neuron 1.16.0.

To see details of Neuron component versions please see neuron-release-content.

TensorFlow model server

Starting from *Neuron 1.16.0*, TensorFlow Neuron model server will be packaged together with `libnrt.so` and will expect `aws-neuron-dkms` *version 2.1.5.0* or newer for proper operation.

Note: The TensorFlow Neuron model server included in *Neuron 1.16.0* should run from the directory in which it was installed, as it will not run properly if copied to a different location due to its dependency on `libnrt.so`.

Important: Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

Neuron tools

- `neuron-cli` - Starting from *Neuron 1.16.0*, `neuron-cli` enters maintenance mode, see maintenance_neuron-cli for more information.
- `neuron-top` - Starting from *Neuron 1.16.0*, `neuron-top` has a new user interface, see *Neuron Top User Guide* for more information.
- `neuron-monitor` - `neuron-monitor` was updated to support Neuron Runtime 2.x (`libnrt.so`)
  - See *Neuron Monitor User Guide* for a updated user guide of `neuron-monitor`.
  - See neuron-monitor-upg for a list of changes between *Neuron Monitor 2.x* and *Neuron Monitor 1.0*
  - See neuron-monitor-bwc for how you can use *Neuron Monitor 2.x* with *Neuron Runtime 1.x* (`neuron-rtd`) .

19.2.4 How will this change affect me?

Neuron installation and upgrade

As explained in "*How will this change affect the Neuron SDK?*", starting from *Neuron 1.16.0*, `libnrt.so` requires the latest Neuron Driver (`aws-neuron-dkms`), in addition there is no longer the need to install `aws-neuron-runtime`. To install Neuron or upgrade to latest Neuron version, please follow the installation and upgrade instructions below:

- **PyTorch Neuron**
  - *Install PyTorch Neuron (torch-neuron)*.
  - *Update to latest PyTorch Neuron (torch-neuron)*.
- **TensorFlow Neuron**
  - *Install TensorFlow Neuron*.
  - *Update to latest TensorFlow Neuron*.
- **MXNet Neuron**
  - *Install MXNet Neuron*.
  - *Update to latest MXNet Neuron*.

Important: Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

Migrate your application to Neuron Runtime 2.x (libnrt.so)

For a successful migration of your application to *Neuron 1.16.0* or newer from previous releases, please make sure you perform the following:

1. **Prerequisite** Please read "*How will this change affect the Neuron SDK?*" section.
2. **Make sure you are not using *Neuron Runtime 1.x* (`aws-neuron-runtime`)**
   - Remove any code that install `aws-neuron-runtime` from any CI/CD scripts.
   - Stop `neuron-rtd` by running: `sudo systemctl stop neuron-rtd`
   - Uninstall `neuron-rtd` by running: `sudo apt remove aws-neuron-runtime` or `sudo yum remove aws-neuron-runtime`
3. **Upgrade to your Neuron Framework of choice:**
   - *Update to latest PyTorch Neuron (torch-neuron)*.
   - *Update to latest TensorFlow Neuron*.
   - *Update to latest MXNet Neuron*.
4. **If you have a code that start and/or stop `neuron-rtd`** Remove any code that start or stop `neuron-rtd` from any CI/CD scripts.
5. **Application running multiple `neuron-rtd`** If your application runs multiple processes and required running multiple `neuron-rtd` daemons:
   - Remove the code that runs multiple `neuron-rtd` daemons.

- Instead of allocating Neuron devices to `neuron-rtd` through configuration files, use `NEURON_RT_VISIBLE_CORES` or `NEURON_RT_NUM_CORES` environment variables to allocate NeuronCores. See *Neuron Runtime Configuration* for details.

If you application uses `NEURONCORE_GROUP_SIZES`, see next item.

Note: `NEURON_RT_VISIBLE_CORES` and `NEURON_RT_NUM_CORES` environment variables enables you to allocate NeuronCores to an application. Allocating NeuronCores improves application granularity because Neuron device include multiple NeuronCores.

---

6. **Application running multiple processes using `NEURONCORE_GROUP_SIZES`**

   - Please consider using `NEURON_RT_VISIBLE_CORES` or `NEURON_RT_NUM_CORES` environment variables instead of `NEURONCORE_GROUP_SIZES` as it is being deprecated,

   see *Neuron Runtime Configuration* for details.

   - If you using TensorFlow Neuron (`tensorflow-nueron (TF2.x)`) and you are replacing `NEURONCORE_GROUP_SIZES=AxB` which enables auto multicore replication, please see the new api *TensorFlow Neuron (tensorflow-nueron) Auto Multicore Replication (Experimental)* for usage and documentation.
   - Your application behavior will remain the same as before if you do not set `NEURON_RT_VISIBLE_CORES` and do not set `NEURON_RT_NUM_CORES`.
   - If you are considering migrating to `NEURON_RT_VISIBLE_CORES` or `NEURON_RT_NUM_CORES`, please use the following guidelines:
     - `NEURON_RT_VISIBLE_CORES` takes precedence over `NEURON_RT_NUM_CORES`.
     - If you are migrating to `NEURON_RT_VISIBLE_CORES`:
       * For TensorFlow applications or PyTorch applications make sure that `NEURONCORE_GROUP_SIZES` is unset, or that `NEURONCORE_GROUP_SIZES` allocate the same or less number of NeuronCores allocated by `NEURON_RT_VISIBLE_CORES`.
       * For MXNet applications, setting `NEURONCORE_GROUP_SIZES` and `NEURON_RT_VISIBLE_CORES` environment variables at the same time is not supported. Please use `NEURON_RT_VISIBLE_CORES` only.
       * See *Neuron Runtime Configuration* for more details of how to use `NEURON_RT_VISIBLE_CORES`.
     - If you are migrating to `NEURON_RT_NUM_CORES`:
       * Make sure that `NEURONCORE_GROUP_SIZES` is unset.
       * See *Neuron Runtime Configuration* for more details of how to use `NEURON_RT_NUM_CORES`.

7. **Application running multiple processes accessing same NeuronCore** If your application accesses the same NeuronCore from multiple processes, this is no longer possible with `libnrt.so`. Instead, please modify your application to access the same NeuronCore from multiple threads.

Note: For optimal performance of multi-model execution, each NeuronCore should execute a single model.

---

8. **Neuron Tools**

   - If you are using Neuron Monitor, see neuron-monitor-upg for details.

- If you are using `neuron-cli` please remove any call to `neuron-cli`. For more information, see maintenance_neuron-cli.

9. **Containers** If your application is running within a container, and it previously executed `neuron-rtd` within the container, you need to re-build your container so it will not include or install `aws-neuron-runtime`. See neuron-containers and containers-migration-to-runtime2 for details.

19.2.5 Troubleshooting

Application fails to start

Description

Starting from *Neuron 1.16.0* release, Neuron Runtime (`libnrt.so`) requires *Neuron Driver 2.0* or greater (`aws-neuron-dkms`). Neuron Runtime requires Neuron Driver(`aws-neuron-dkms` package) to access Neuron devices.

If `aws-neuron-dkms` is not installed then the application will fail with an error message on console and syslog that look like the following:

```
NRT:nrt_init      Unable to determine Neuron Driver version. Please check aws-neuron-
↪dkms package is installed.
```

If an old `aws-neuron-dkms` is installed then the application will fail with an error message on console and syslog that look like the following:

```
NRT:nrt_init      This runtime requires Neuron Driver version 2.0 or greater. Please␣
↪upgrade aws-neuron-dkms package.
```

Solution

Please follow the installation steps in install-guide-index to install `aws-neuron-dkms`.

Important: Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

Application fails to start although I installed latest `aws-neuron-dkms`

Description

Starting from *Neuron 1.16.0* release, Neuron Runtime (`libnrt.so`) require *Neuron Driver 2.0* or greater (`aws-neuron-dkms`). If an old `aws-neuron-dkms` is installed, the application will fail. You may try to install `aws-neuron-dkms` and still face application failure, this may happen because the `aws-neuron-dkms` installation failed as a result of `neuron-rtd` daemon that is still running .

Solution

- Stop `neuron-rtd` by running: `sudo systemctl stop neuron-rtd`
- Uninstall `neuron-rtd` by running: `sudo apt remove aws-neuron-runtime` or `sudo yum remove aws-neuron-runtime`
- Install `aws-neuron-dkms` by following steps in install-guide-index

Important: Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

Application unexpected behavior when upgrading to release *Neuron 1.16.0* or newer

Description

When upgrading to release *Neuron 1.16.0* or newer from previous releases, the OS may include two different versions of *Neuron Runtime*: the `libnrt.so` shared library and `neuron-rtd` daemon. This can happen if the user didn't stop `neuron-rtd` daemon or didn't make sure to uninstall the existing Neuron version before upgrade. In this case the user application may behave unexpectedly.

Solution

If the OS includes two different versions of *Neuron Runtime*, `libnrt.so` shared library and `neuron-rtd` daemon:

- Before running applications that use `neuron-rtd`, restart `neuron-rtd` by calling `sudo systemctl restart neuron-rtd`.
- Before running applications linked with `libnrt.so`, stop `neuron-rtd` by calling `sudo systemctl stop neuron-rtd`.

Application unexpected behavior when downgrading to releases before *Neuron 1.6.0* (from *Neuron 1.16.0* or newer)

Description

When upgrading to release *Neuron 1.16.0* or newer from previous releases, and then downgrading back to releases before *Neuron 1.6.0*, the OS may include two different versions of *Neuron Runtime*: the `libnrt.so` shared library and `neuron-rtd` daemon. This can happen if the user didn't make sure to uninstall the existing Neuron version before upgrade or downgrade. In this case the user application may behave unexpectedly.

Solution

If the OS include two different versions of *Neuron Runtime*, `libnrt.so` shared library and `neuron-rtd` daemon:

- Before running applications that use `neuron-rtd`, restart `neuron-rtd` by calling `sudo systemctl restart neuron-rtd`.
- Before running applications linked with `libnrt.so`, stop `neuron-rtd` by calling `sudo systemctl stop neuron-rtd`.

Neuron Core is in use

Description

A Neuron Core can't be shared between two applications. If an application started using a Neuron Core all other applications trying to use the NeuronCore would fail during runtime initialization with the following message in the console and in syslog:

```
ERROR   NRT:nrt_allocate_neuron_cores               NeuronCore(s) not available -␣
↪Requested:nc1-nc1 Available:0
```

Solution

Terminate the the process using NeuronCore and then try launching the application again.

19.2.6 Frequently Asked Questions (FAQ)

Do I need to recompile my model to run it with Neuron Runtime 2.x (`libnrt.so`)?

No.

Do I need to change my application launch command?

No.

Can `libnrt.so` and `neuron-rtd` co-exist in the same environment?

Although we recommend upgrading to the latest Neuron release, we understand that for a transition period you may continue using `neuron-rtd` for old releases. If you are using Neuron Framework (PyTorch,TensorFlow or MXNet) from releases before *Neuron 1.16.0*:

- Install the latest Neuron Driver (`aws-neuron-dkms`)

Important: Starting Neuron version 2.3, `aws-neuron-dkms` package name is changed to `aws-neuronx-dkms`, see *Introducing first release of Neuron 2.x enabling EC2 Trn1 general availability (GA)*

- For development, we recommend using different environments for Neuron Framework (PyTorch,TensorFlow or MXNet) from releases before *Neuron 1.16.0* and for Neuron Framework (PyTorch,TensorFlow or MXNet) from *Neuron 1.16.0* and newer, if that is not possible, please make sure to stop `neuron-rtd` before executing models using Neuron Framework (PyTorch,TensorFlow or MXNet) from *Neuron 1.16.0* and newer.

- For deployment, when you are ready to upgrade, please upgrade to Neuron Framework (PyTorch,TensorFlow or MXNet) from *Neuron 1.16.0* and newer. see *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for more information.

Warning: Executing models using Neuron Framework (PyTorch,TensorFlow or MXNet) from *Neuron 1.16.0* and newer in an environment where `neuron-rtd` is running may cause undefined behavior. Please make sure to stop `neuron-rtd` before executing models using Neuron Framework (PyTorch,TensorFlow or MXNet) from *Neuron 1.16.0* and newer.

Are there Neuron framework versions that will not support Neuron Runtime 2.x (`libnrt.so`)?

All supported PyTorch Neuron and TensorFlow framework extensions in addition to Neuron MXnet 1.8.0 framework extensions support Neuron Runtime 2.x.

Neuron MxNet 1.5.1 does not support Neuron Runtime 2.x (`libnrt.so`) and has now entered maintenance mode. Please see maintenance_mxnet_1_5 for details.

Performance (Inf1)

This document is relevant for: `Inf1`

19.3 Performance Tuning

Important: NeuronCore Groups (NCG) is deprecated, please see eol-ncg and *Migrate your application to Neuron Runtime 2.x (libnrt.so)* for more details.

This guide is intended to provide the reader with an in-depth understanding on how to optimize neural network performance on Inferentia for both throughput and latency. For simplicity, the guide uses TensorFlow and ResNet-50 model as a teaching example to learn how choosing between different compile-time optimizations (e.g. Batching and NeuronCore Pipeline), as well as model-serving optimizations (e.g. multi-threading and dynamic-batching) improves inference performance.

The following guides are considered prerequisites for this tutorial:

- *Running ResNet50 on Inferentia*
- tensorflow-serving-neurocore-group
- *Neuron Batching*
- *NeuronCore Pipeline*

19.3.1 Batching and pipelining (technical background)

Neuron provides developers with various performance optimization features.

Two of the most widely used features are batching and pipelining. Both techniques aim to keep the data close to the compute engines, but achieve this data locality in different ways. In batching it is achieved by loading the data into an on-chip cache and reusing it multiple times for multiple different model-inputs, while in pipelining this is achieved by caching all model parameters into the on-chip cache across multiple NeuronCores and streaming the calculation across them.

As a general rule of thumb, batching is preferred for applications that aim to optimize throughput and cost at the expense of latency, while pipelining is preferred for applications with high-throughput requirement under a strict latency budget.

19.3.2 Compiling for batching optimization

To enable the batching optimization, we first need to compile the model for a target batch-size. This is done by specifying the batch size in the input tensor's batch dimension during compilation. Users are encouraged to evaluate multiple batch sizes in order to determine the optimal latency/throughput deployment-point, which is application dependent.

For example, the code snippet below enables batching on a ResNet50 model, with a batch-size of 5:

```
import numpy as np
import tensorflow.neuron as tfn

# To change the batch size, change the first dimension in example_input
batch_size = 5
example_input = np.zeros([batch_size,224,224,3], dtype='float16')

tfn.saved_model.compile("rn50_fp16",
                        "rn50_fp16_compiled/1",
                        model_feed_dict={'input_1:0': example_input },
                        dynamic_batch_size=True)
```

Note: Depending on the neural network size, Neuron will have a maximum batch size that works optimally on Inferentia. If an unsupported batch size is used, an internal compiler error message will be displayed. A simple way to explore optimal batch size for your specific model is to increment the batch size from 1 upward, one at a time, and test application performance.

19.3.3 Compiling for pipeline optimization

With NeuronCore Pipeline mode, Neuron stores the model parameters onto the Inferentias' local caches, and streams the inference requests across the available NeuronCores, as specified by the `--neuroncore-pipeline-cores` compiler argument. For example, to compile the model to fit pipeline size of four Inferentia devices (16 NeuronCores) avaliable in the inf1.6xlarge instance size:

```
import numpy as np
import tensorflow.neuron as tfn

compiler_args = ['--neuroncore-pipeline-cores', '16']
example_input = np.zeros([1,224,224,3], dtype='float16')
tfn.saved_model.compile("rn50_fp16",
```

(continues on next page)

(continued from previous page)

```
                                "rn50_fp16_compiled/1",
                                model_feed_dict={'input_1:0': example_input },
                                compiler_args=compiler_args)
```

The minimum number of NeuronCores needed to run a compiled model can be found using Neuron Check Model tool. Please see *Neuron Check Model*.

19.3.4 Model-serving inference optimizations

In order to fully realize the maximum throughput of the compiled model (for either batching and pipelining), users need to launch multiple host CPU threads to feed inputs into the Neuron pipeline. The number of threads need to be larger than the specified maximum number of NeuronCores.

Additionally, dynamic batching (framework optimization currently supported only by TensorFlow-Neuron) can be used to process a larger client-side inference batch-size and the framework automatically breaks up the user-batch into smaller batch sizes to match the compiled batch-size. This technique increases the achievable throughput by hiding the framework-to-neuron overhead, and amortizing it over a larger batch size. To use dynamic batching, set the argument `--dynamic_batch_size=True` during compilation and send larger inference batch size (user inference batch size) that is equal to a multiple of the compiled batch size.

Both of methods can be applied together if that shows improvement in performance. However, multi-threading is always needed as a first step to achieve high throughput. You may need to experiment in order to find the right optimization settings for your application.

By default, the framework sets the number of outstanding inference requests to the total number of NeuronCores plus three. This can be changed by setting the NEURON_MAX_NUM_INFERS environment variable. For example, if the compiled model includes some CPU partitions (as when Neuron compiler decided some operations are more efficient to execute on CPU), the number of threads should be increased to account for the additional compute performed on the CPU. Note that the available instance host memory size should be taken into consideration to avoid out-of-memory errors. As above, you need to experiment in order to find the right optimization settings for your application.

Note: By default the framework allocates NeuronCore Group size to match the size of the compiled model. The size of the model is the number of NeuronCores limit passed to compiler during compilation (`--neuroncore-pipeline-cores` option). For more information see tensorflow-serving-neurocore-group.

19.3.5 Other considerations

Mixed Precision

You can find more defails about performance and accuracy trade offs in *Mixed precision and performance-accuracy tuning (neuron-cc)*.

Operator support

The Neuron Compiler maintains an evolving list of supported operators for each framework: *Neuron Supported operators*

AWS Neuron handles unsupported operators by partitioning the graph into subgraph, and executing them on different targets (e.g. NeuronCore partition, CPU partition). If the entire model can run on Inferentia (i.e. all operators are supported), then the model will be compiled into a single subgraph which will be executed by a NeuronCore Group.

Debug

You can examine the post-compiled model to view the compilation results using the Neuron plugin for TensorBoard. See *Visualize graphs executed on Neuron*.

19.3.6 ResNet-50 optimization example

For an example demonstrating the concepts described here, see *Tensorflow ResNet 50 Optimization Tutorial*

This document is relevant for: `Inf1`

This document is relevant for: `Inf1`

19.4 Parallel Execution using NEURON_RT_NUM_CORES

Important: `NEURONCORE_GROUP_SIZES` will no longer be supported starting Neuron 1.19.0 release if your application is using `NEURONCORE_GROUP_SIZES` please see *Migrate your application to Neuron Runtime 2.x (libnrt.so)* and eol-ncgs-env_2 for more details.

19.4.1 Introduction

Inf1 instances are available with a different number of Inferentia chips, each Inferentia chip is combined of 4 NeuronCores and an Inf1 instance includes 4 to 64 NeuronCores depending on the instance size. This guide will show you how to load one or more compiled models into different consecutive groups of NeuronCores using your framework of choice.

19.4.2 Data Parallel Execution

In PyTorch and TensorFlow, the same compiled model can run in parallel on an Inf1 instance by loading it multiple times, up to the total number of NeuronCores specified in NEURON_RT_NUM_CORES or NEURON_RT_VISIBLE_CORES. For more information about NEURON_RT_NUM_CORES and NEURON_RT_VISIBLE_CORES, please refer to *Neuron Runtime Configuration*.

Running multiple models using single process

To run multiple models using single process, you set the environment variable `NEURON_RT_NUM_CORES` with a comma separated list of number of cores in each group.

You can set `NEURON_RT_NUM_CORES` environment variable at runtime:

```
#!/bin/bash
NEURON_RT_NUM_CORES=13 python your_neuron_application.py
```

Or from within your python process running your models (NOTE: you can only set it once in the same process at the beginning of the script):

```
#!/usr/bin/env python
import os

# Set Environment
os.environ['NEURON_RT_NUM_CORES']='13'

# Load models and run inferences ...
```

The below examples allow you to load 4 models into 4 groups of NeuronCores within one process. For example, if there are 4 models A, B, C, D compiled to 2, 4, 3, and 4 NeuronCores respectively, you directly load the models A, B, C, D in sequence within your TensorFlow or PyTorch Neuron process. This example requires an inf1.6xlarge instance with 16 NeuronCores, as the total number of NeuronCores within the NeuronCore Groups is 13.

In MXNet, the mapping from models to NeuronCores is controlled by context `mx.neuron(neuron_core_index)` where `neuron_core_index` is the NeuronCore index at the start of the group. In the example above, you map model A to `mx.neuron(0)` context, model B to `mx.neuron(2)` context, model C to `mx.neuron(6)` context and model D to `mx.neuron(9)` context. For further details, please refer to *Flexible Execution Group (FlexEG) in Neuron-MXNet*.

For PyTorch

For an automated data parallel solution in PyTorch, please see *Data Parallel Inference on Torch Neuron* for more details.

For Tensorflow

```
# Set Environment
os.environ['NEURON_RT_NUM_CORES']='13'

# Load models (TF2)
model0 = tf.keras.models.load_model(model0_file) # loaded into the first group of NC0-NC1
model1 = tf.keras.models.load_model(model1_file) # loaded into the second group of NC2-
↪NC5
model2 = tf.keras.models.load_model(model1_file) # loaded into the third group of NC6-NC8
model3 = tf.keras.models.load_model(model1_file) # loaded into the fourth group of NC9-
↪NC12

# run inference by simply calling the loaded model
results0 = model0(inputs0)
results1 = model1(inputs1)
results2 = model2(inputs2)
results3 = model3(inputs3)
```

For MXNet 2.x:

```
# Set Environment
os.environ['NEURON_RT_NUM_CORES']='13'

# Load models (MXNet)
# loaded into the first group of NC0-NC1
sym, args, aux = mx.model.load_checkpoint(mx_model0_file, 0)
model0 = sym.bind(ctx=mx.neuron(0), args=args, aux_states=aux, grad_req='null')
# loaded into the second group of NC2-NC5
sym, args, aux = mx.model.load_checkpoint(mx_model1_file, 0)
model1 = sym.bind(ctx=mx.neuron(2), args=args, aux_states=aux, grad_req='null')
# loaded into the third group of NC6-NC8
sym, args, aux = mx.model.load_checkpoint(mx_model2_file, 0)
model2 = sym.bind(ctx=mx.neuron(6), args=args, aux_states=aux, grad_req='null')
# loaded into the fourth group of NC9-NC12
sym, args, aux = mx.model.load_checkpoint(mx_model3_file, 0)
model3 = sym.bind(ctx=mx.neuron(9), args=args, aux_states=aux, grad_req='null')

# run inference by simply calling the loaded model
results0 = model0.forward(data=inputs0)
results1 = model1.forward(data=inputs1)
results2 = model2.forward(data=inputs2)
results3 = model3.forward(data=inputs3)
```

You can identify the NeuronCores used by each application using the `neuron-top` command line tool. For more information about the neuron-top user interface, please see *Neuron Top User Guide*.

```
$ neuron-top
```

Running multiple models using multiple processes

You can also run multiple models in parallel processes, when you set NEURON_RT_NUM_CORES per process:

```
$ NEURON_RT_NUM_CORES=2 python your_1st_neuron_application.py
$ NEURON_RT_NUM_CORES=2 python your_2nd_neuron_application.py
```

The first process automatically selects a first set of 2 unused NeuronCores for its new group. The second process automatically selects a new set of 2 unused NeuronCores for its new group.

Running multiple models on the same NeuronCore group

You can load more than one model in a NeuronCore group within one process. The Neuron runtime will handle switching from one model to the next model within the NeuronCore group when the next model is run within the application. In TensorFlow or PyTorch, simply load the additional models after the initial number of models have been loaded, to fill the NeuronCore groups associated with the process.

For PyTorch:

```
# Set Environment
os.environ['NEURON_RT_NUM_CORES']='2'

# Load models (PT)
model0 = torch.jit.load(model0_file) # loaded into the first group of NC0-NC1
model1 = torch.jit.load(model1_file) # loaded into the first group of NC0-NC1

# run inference by simply calling the loaded model
results0 = model0(inputs0)
results1 = model1(inputs1)
```

For TensorFlow 2.x:

```
# Set Environment
os.environ['NEURON_RT_NUM_CORES']='2'
```

(continues on next page)

(continued from previous page)

```
# Load models (TF2)
model0 = tf.keras.models.load_model(model0_file) # loaded into the first group of NC0-NC1
model1 = tf.keras.models.load_model(model1_file) # loaded into the first group of NC0-NC1

# run inference by simply calling the loaded model
results0 = model0(inputs0)
results1 = model1(inputs1)
```

In MXNet, use context `mx.neuron(neuron_core_index)` and use the same NeuronCore start index for the additional models.

```
# Set Environment
os.environ['NEURON_RT_NUM_CORES']='2'

# Load models (MXNet)
# loaded into the first group of NC0-NC1
sym, args, aux = mx.model.load_checkpoint(mx_model0_file, 0)
model0 = sym.bind(ctx=mx.neuron(0), args=args, aux_states=aux, grad_req='null')
# loaded into the first group of NC0-NC1
sym, args, aux = mx.model.load_checkpoint(mx_model1_file, 0)
model1 = sym.bind(ctx=mx.neuron(0), args=args, aux_states=aux, grad_req='null')

# run inference by simply calling the loaded model
results0 = model0.forward(data=inputs0)
results1 = model1.forward(data=inputs1)
```

The total `NEURON_RT_NUM_CORES` across all processes cannot exceed the number of NeuronCores available on the instance. For example, on an inf1.xlarge with default configurations where the total number of NeuronCores visible to TensorFlow-Neuron is 4, you can launch one process with `NEURON_RT_NUM_CORES=2` (pipelined) and another process with `NEURON_RT_NUM_CORES=2` (data-parallel).

Examples using `NEURON_RT_NUM_CORES` include:

- *PyTorch example*
- *MXNet example*

19.4.3 Auto Model Replication in TensorFlow Neuron (`tensorflow-neuron`) (Experimental)

Please see the below API documentation to see how to perform automatic replication on multiple cores. Note that the automatic replication will only work on models compiled with pipeline size 1: via `--neuroncore-pipeline-cores=1`. If auto replication is not enabled, the model will default to replicate on up to 4 cores.

Python API (TF 2.x only):

TensorFlow Neuron (tensorflow-nueron) Auto Multicore Replication (Experimental)

CLI API (TF 1.x and TF 2.x):

TensorFlow Neuron TF1.x/TF2.x (tensorflow-nueron TF1.x/TF2.x) Auto Multicore Replication CLI (Experimental)

19.4.4 Auto Model Replication (Being Deprecated)

The Auto Model Replication feature in TensorFlow-Neuron enables you to load the model once and the data parallel replication would happen automatically. This reduces framework memory usage as you are not loading the same model multiple times. This feature is experimental and available in TensorFlow-Neuron only.

To enable Auto Model Replication, set NEURONCORE_GROUP_SIZES to Nx1 where N is the desired replication count (the number of NeuronCore groups, each group has size 1). For example, NEURONCORE_GROUP_SIZES=8x1 would automatically replicate the single-NeuronCore model 8 times.

```
os.environ['NEURONCORE_GROUP_SIZES'] = '4x1'
```

or

```
NEURONCORE_GROUP_SIZES=4x1 python3 application.py
```

When NEURONCORE_GROUP_SIZES is not set, the default is 4x1 where a single-NeuronCore model is replicated 4 times on any sized inf1 machine.

This feature is only available for models compiled with neuroncore-pipeline-cores set to 1 (default).

You will still need to use threads in the scaffolding code to feed the loaded replicated model instance in order to achieve high throughput.

Example of auto model replication: *Running OpenPose on Inferentia*

19.4.5 FAQ

Can I mix data parallel and NeuronCore Pipeline?

Yes. You can compile the model using neuroncore-pipeline-cores option. This tells the compiler to set compilation to the specified number of cores for *NeuronCore Pipeline*. The Neuron Compiler will return a NEFF which fits within this limit. See the *Neuron compiler CLI Reference Guide (neuron-cc)* on how to use this option.

For example, on an inf1.2xlarge, you can load two model instances, each compiled with neuroncore-pipeline-cores set to 2, so that they can run in parallel. The model instances can be loaded from different saved models or from the same saved model.

Can I have a mix of multiple models in one Neuroncore group and single model in another one Neuroncore group?

Currently, you can do this in MXNet by setting up two Neuroncore groups, then load for example multiple models in one NCG using context mx.neuron(0), and load single model in the second NCG using context mx.neuron(2). You can also load single model in the first NCG and multiple models in the second NCG. For example:

```
# Set Environment
os.environ['NEURON_RT_NUM_CORES']='6'

# Load models (MXNet)
# loaded into the first group of NC0-NC1
sym, args, aux = mx.model.load_checkpoint(mx_model0_file, 0)
model0 = sym.bind(ctx=mx.neuron(0), args=args, aux_states=aux, grad_req='null')
# loaded into the second group of NC2-NC5
sym, args, aux = mx.model.load_checkpoint(mx_model1_file, 0)
```

(continues on next page)

(continued from previous page)

```
model1 = sym.bind(ctx=mx.neuron(2), args=args, aux_states=aux, grad_req='null')
# loaded into the second group of NC2-NC5
sym, args, aux = mx.model.load_checkpoint(mx_model2_file, 0)
model2 = sym.bind(ctx=mx.neuron(2), args=args, aux_states=aux, grad_req='null')
# loaded into the second group of NC2-NC5
sym, args, aux = mx.model.load_checkpoint(mx_model3_file, 0)
model3 = sym.bind(ctx=mx.neuron(2), args=args, aux_states=aux, grad_req='null')

# run inference by simply calling the loaded model
results0 = model0.forward(data=inputs0)
results1 = model1.forward(data=inputs1)
results2 = model2.forward(data=inputs2)
results3 = model3.forward(data=inputs3)
```

Loading multiple models in one NCG and single model in another NCG is currently not supported in TensorFlow and PyTorch.

19.5.1 R-CNN Model Overview

Region-based CNN (R-CNN) models are commonly used for object detection and image segmentation tasks. A typical R-CNN architecture is composed of the following components:

- **Backbone:** The backbone extracts features from input images. In some models, the backbone is a Feature Pyramid Network (FPN), which uses a top-down architecture with lateral connections to build an in-network feature pyramid from a single-scale input. The backbone is commonly a ResNet or Vision Transformer based network.
- **Region Proposal Network (RPN):** The RPN predicts region proposals with a wide range of scales and aspect ratios. RPNs are constructed using convolutional layers and anchor boxes that serve as references for multiple scales and aspect ratios.
- **Region of Interest (RoI):** The RoI component is used to resize the extracted features that have varying size to the same size so that they can be consumed by a fully connected layer. RoI Align is typically used instead of RoI Pooling because RoI Align provides better alignment.

The Detectron2 library provides many popular PyTorch R-CNN implementations, including R-CNN, Fast R-CNN, Faster R-CNN, and Mask R-CNN. This application note will focus on the Detectron2 R-CNN models.

R-CNN Limitations and Considerations on Inferentia (NeuronCore-v1)

R-CNN models can have a few limitations and considerations on Inferentia (NeuronCore-v1). See the *Model Architecture Fit Guidelines* for more information. These limitatins are not applicable to NeuronCore-v2.

19.5.2 Requirements

This application note is intended to be run on an `inf1.2xlarge`. In practice, R-CNN models can be run on any Inf1 instance size.

Verify that this Jupyter notebook is running the Python kernel environment that was set up according to the PyTorch Installation Guide. You can select the kernel from the "Kernel -> Change Kernel" option on the top of this Jupyter notebook page.

19.5.3 Installation

This application note requires the following pip packages:

1. `torch==1.11.0`
2. `torch-neuron`
3. `neuron-cc`
4. `opencv-python`
5. `pycocotools`

6. `torchvision==0.12.0`
7. `detectron2==0.6`

The following section builds `torchvision` from source and installs the `Detectron2` package. It also reinstalls the Neuron packages to ensure version compability.

The the `torchvision` `roi_align_kernel.cpp` kernel is modified to use OMP threading for multithreaded inference on CPU. This significantly improves the performance of RoI Align kernels on Inf1: OMP threading leads to a 2 - 3x RoI Align latency reduction compared to the default `roi_align_kernel.cpp` kernel configuration.

```
# Install python3.7-dev for pycocotools (a Detectron2 dependency)
!sudo apt install python3.7-dev -y

# Install Neuron packages
!pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com
!pip uninstall -y torchvision
!pip install --force-reinstall torch-neuron==1.11.0.* neuron-cc[tensorflow] "protobuf==3.
↪20.1" ninja opencv-python

# Change cuda to 10.2 for Detectron2
!sudo rm /usr/local/cuda
!sudo ln -s /usr/local/cuda-10.2 /usr/local/cuda

# Install Torchvision 0.12.0 from source
!git clone -b release/0.12 https://github.com/pytorch/vision.git

# Update the RoI Align kernel to use OMP multithreading
with open('vision/torchvision/csrc/ops/cpu/roi_align_kernel.cpp', 'r') as file:
    content = file.read()

# Enable OMP Multithreading and set the number of threads to 4
old = "// #pragma omp parallel for num_threads(32)"
new = "#pragma omp parallel for num_threads(4)"
content = content.replace(old, new)

# Re-write the file
with open('vision/torchvision/csrc/ops/cpu/roi_align_kernel.cpp', 'w') as file:
    file.write(content)

# Build Torchvision with OMP threading
!cd vision && CFLAGS="-fopenmp" python setup.py bdist_wheel
%pip install vision/dist/*.whl

# Install Detectron2 release v0.6
!python -m pip install 'git+https://github.com/facebookresearch/detectron2.git@v0.6'
```

19.5.4 Compiling an R-CNN for Inf1

By default, R-CNN models are not compilable on Inf1 because they cannot be traced with `torch.jit.trace`, which is a requisite for inference on Inf1. The following section demonstrates techniques for compiling a Detectron2 R-CNN model for inference on Inf1.

Specifically, this section creates a standard Detectron2 R-CNN model using a ResNet-101 backbone. It demonstrates how to use profiling to identify the most compute intensive parts of the R-CNN that should be compiled for accelerated inference on Inf1. It then explains how to manually extract and compile the ResNet backbone (the dominant compute component) and inject the compiled backbone back into the full model for improved performance.

Create a Detectron2 R-CNN Model

We create a Detectron2 R-CNN model using the `COCO-Detection/faster_rcnn_R_101_FPN_3x.yaml` pretrained weights and config file. We also download a sample image from the COCO dataset and run an example inference.

```
from detectron2 import model_zoo
from detectron2.engine import DefaultPredictor
from detectron2.config import get_cfg

def get_model():

    # Configure the R-CNN model
    CONFIG_FILE = "COCO-Detection/faster_rcnn_R_101_FPN_3x.yaml"
    WEIGHTS_FILE = "COCO-Detection/faster_rcnn_R_101_FPN_3x.yaml"
    cfg = get_cfg()
    cfg.merge_from_file(model_zoo.get_config_file(CONFIG_FILE))
    cfg.MODEL.WEIGHTS = model_zoo.get_checkpoint_url(WEIGHTS_FILE)
    cfg.MODEL.ROI_HEADS.SCORE_THRESH_TEST = 0.5
    cfg.MODEL.DEVICE = 'cpu'  # Send to CPU for Neuron Tracing

    # Create the R-CNN predictor wrapper
    predictor = DefaultPredictor(cfg)
    return predictor
```

```
import os
import urllib.request

# Define a function to get a sample image
def get_image():
    filename = 'input.jpg'
    if not os.path.exists(filename):
        url = "http://images.cocodataset.org/val2017/000000439715.jpg"
        urllib.request.urlretrieve(url, filename)
    return filename
```

```
import time
import cv2

# Create an R-CNN model
predictor = get_model()

# Get a sample image from the COCO dataset
```

(continues on next page)

(continued from previous page)

```
image_filename = get_image()
image = cv2.imread(image_filename)

# Run inference and print inference latency
start = time.time()
outputs = predictor(image)
print(f'Inference time: {(time.time() - start):0.3f} s')
```

Profile the Model

We can use the PyTorch Profiler to identify which operators contribute the most to the model's runtime on CPU. Ideally, we can compile these compute intensive operators onto Inf1 for accelerated inference.

```
import torch.autograd.profiler as profiler

with profiler.profile(record_shapes=True) as prof:
    with profiler.record_function("model_inference"):
        predictor(image)
print(prof.key_averages().table(sort_by="cpu_time_total", row_limit=30))
```

We see that convolution operators (`aten::convolution`) contribute the most to the inference time. By compiling these convolution operators to Inf1, we can improve performance of the R-CNN model. We can print the R-CNN model architecture to see which layers contain the `aten::convolution` operators:

```
print(predictor.model)
```

We observe that the ResNet FPN backbone (predictor.model.backbone L17-L162) contains the majority of convolution operators in the model. The RPN (predictor.model.proposal_generator L181-L533) also contains a few convolutions. Based on this, we should try to compile the ResNet backbone and RPN onto Inf1 to maximize performance.

Compiling the ResNet backbone to Inf1

In this section we demonstrate how to compile the ResNet backbone to Inf1 and use it for inference.

We "extract" the backbone by accessing it using `predictor.model.backbone`. We compile the backbone using `strict=False` because the backbone outputs a dictionary. We use a fixed input shape (`800 x 800`) for compilation. This will be the input shape that all inputs will be resized to during inference. This section also defines a basic pre-processing function (mostly derived from the Detectron2 R-CNN DefaultPredictor module L308-L318) that reshapes inputs to `800 x 800`.

We also create a `NeuronRCNN` wrapper that we use to inject the compiled backbone back into the model by dynamically replacing the `predictor.model.backbone` attribute with the compiled model.

```
import torch
import torch_neuron

example = torch.rand([1, 3, 800, 800])

# Use `with torch.no_grad():` to avoid a jit tracing issue in the ResNet backbone
with torch.no_grad():
    neuron_backbone = torch_neuron.trace(predictor.model.backbone, example, strict=False)
```

(continues on next page)

(continued from previous page)

```
backbone_filename = 'backbone.pt'
torch.jit.save(neuron_backbone, backbone_filename)
```

```
from detectron2.modeling.meta_arch.rcnn import GeneralizedRCNN
from torch.jit import ScriptModule

class NeuronRCNN(torch.nn.Module):
    """
    Creates a `NeuronRCNN` wrapper that injects the compiled backbone into
    the R-CNN model. It also stores the `size_divisibility` attribute from
    the original backbone.
    """

    def __init__(self, model: GeneralizedRCNN, neuron_backbone: ScriptModule) -> None:
        super().__init__()

        # Keep track of the backbone variables
        size_divisibility = model.backbone.size_divisibility

        # Load and inject the compiled backbone
        model.backbone = neuron_backbone

        # Set backbone variables
        setattr(model.backbone, 'size_divisibility', size_divisibility)

        self.model = model

    def forward(self, x):
        return self.model(x)
```

```
# Create the R-CNN with the compiled backbone
neuron_rcnn = NeuronRCNN(predictor.model, neuron_backbone)
neuron_rcnn.eval()

# Print the R-CNN architecture to verify the backbone is now the
# `neuron_backbone` (shows up as `RecursiveScriptModule`)
print(neuron_rcnn)
```

```
def preprocess(original_image, predictor):
    """
    A basic preprocessing function that sets the input height=800 and
    input width=800. The function is derived from the preprocessing
    steps in the Detectron2 `DefaultPredictor` module.
    """

    height, width = original_image.shape[:2]
    resize_func = predictor.aug.get_transform(original_image)
    resize_func.new_h = 800 # Override height
    resize_func.new_w = 800 # Override width
    image = resize_func.apply_image(original_image)
    image = torch.as_tensor(image.astype("float32").transpose(2, 0, 1))
```

(continues on next page)

(continued from previous page)

```
    inputs = {"image": image, "height": height, "width": width}
    return inputs
```

```
# Get a resized input using the sample image
inputs = preprocess(image, get_model())

# Run inference and print inference latency
start = time.time()
for _ in range(10):
    outputs = neuron_rcnn([inputs])[0]
print(f'Inference time: {((time.time() - start)/10):0.3f} s')
```

```
with profiler.profile(record_shapes=True) as prof:
    with profiler.record_function("model_inference"):
        neuron_rcnn([inputs])
print(prof.key_averages().table(sort_by="cpu_time_total", row_limit=30))
```

By running the backbone on Inf1, the overall runtime is already significantly improved. The count and runtime of `aten::convolution` operators is also decreased. We now see a `neuron::forward_v2` operator which is the compiled backbone.

19.5.5 Optimize the R-CNN model

Compiling the RPN

Looking at the profiling, we see that there are still several `aten::convolution`, `aten::linear`, and `aten::addmm` operators that significantly contribute to the model's overall latency. By inspecting the model architecture and code, we can determine that the majority of these operators are contained in the RPN module (predictor.model.proposal_generator L181-L533).

To improve the model performance, we will extract the RPN Head and compile it on Inf1 to increase the number of operators that are running on Inf1. We only compile the RPN Head because the RPN Anchor Generator contains objects that are not traceable with `torch.jit.trace`.

The RPN Head contains five layers that run inference on multiple resized inputs. In order to compile the RPN Head, we create a list of tensors that contain the input ("`features`") shapes that the RPN Head uses at each layer. These tensor shapes can be determined by printing the input shapes in the RPN Head `forward` function (`predictor.model.proposal_generator.rpn_head.forward`).

We also create a new `NeuronRCNN` wrapper that injects both the compiled backbone and RPN Head into the R-CNN model.

```
import math

input_shape = [1, 3, 800, 800] # Overall input shape at inference time

# Create the list example of RPN inputs using the resizing logic from the RPN Head
features = list()
for i in [0, 1, 2, 3, 4]:
    ratio = 1 / (4 * 2**i)
    x_i_h = math.ceil(input_shape[2] * ratio)
    x_i_w = math.ceil(input_shape[3] * ratio)
```

(continues on next page)

(continued from previous page)

```
    feature = torch.zeros(1, 256, x_i_h, x_i_w)
    features.append(feature)
```

```
# Extract and compile the RPN Head
neuron_rpn_head = torch_neuron.trace(predictor.model.proposal_generator.rpn_head,␣
↪[features])
rpn_head_filename = 'rpn_head.pt'
torch.jit.save(neuron_rpn_head, rpn_head_filename)
```

```
class NeuronRCNN(torch.nn.Module):
    """
    Creates a wrapper that injects the compiled backbone and RPN Head
    into the R-CNN model.
    """

    def __init__(self, model: GeneralizedRCNN, neuron_backbone: ScriptModule, neuron_rpn_
↪head: ScriptModule) -> None:
        super().__init__()

        # Keep track of the backbone variables
        size_divisibility = model.backbone.size_divisibility

        # Inject the compiled backbone
        model.backbone = neuron_backbone

        # Set backbone variables
        setattr(model.backbone, 'size_divisibility', size_divisibility)

        # Inject the compiled RPN Head
        model.proposal_generator.rpn_head = neuron_rpn_head

        self.model = model

    def forward(self, x):
        return self.model(x)
```

```
# Create the R-CNN with the compiled backbone and RPN Head
predictor = get_model()
neuron_rcnn = NeuronRCNN(predictor.model, neuron_backbone, neuron_rpn_head)
neuron_rcnn.eval()

# Print the R-CNN architecture to verify the compiled modules show up
print(neuron_rcnn)
```

```
# Run inference and print inference latency
start = time.time()
for _ in range(10):
    outputs = neuron_rcnn([inputs])[0]
print(f'Inference time: {((time.time() - start)/10):0.3f} s')
```

```
with profiler.profile(record_shapes=True) as prof:
    with profiler.record_function("model_inference"):

```

By running the compiled backbone and RPN Head on Inf1, the overall runtime is improved. Once again, the number and runtime of `aten::convolution` operators is also decreased. We now see two `neuron::forward_v2` operators which correspond to the compiled backbone and RPN Head.

Fusing the Backbone and RPN Head

It is typically preferable to compile fewer independent models ("subgraphs") on Inf1. Combining models and compiling them as a single subgraph enables the Neuron compiler to perform additional optimizations and reduces the I/O data transfer between CPU and NeuronCores between each subgraph.

In this section, we "fuse" the ResNet backbone and RPN Head into a single model that we compile on Inf1. We create the `NeuronFusedBackboneRPNHead` wrapper to create a compilable model that contains both the ResNet backbone (predictor.model.backbone L17-L162) and RPN Head (predictor.model.proposal_generator L181-L533). We also output the `features` because it is used downstream by the RoI Heads. We compile this `NeuronFusedBackboneRPNHead` wrapper as `neuron_backbone_rpn`. We then create a separate `BackboneRPN` wrapper that we use to inject the `neuron_backbone_rpn` in place of the original backbone and RPN Head. We also copy the remainder of the RPN `forward` code (predictor.model.proposal_generator.forward L431-L480) to create a "fused" backbone + RPN module. Lastly, we re-write the `NeuronRCNN` wrapper to use the fused backbone + RPN module. The `NeuronRCNN` wrapper also uses the `predictor.model forward` code to re-write the rest of the R-CNN model forward function.

```
class NeuronFusedBackboneRPNHead(torch.nn.Module):
    """
    Wrapper to compile the fused ResNet backbone and RPN Head.
    """

    def __init__(self, model: GeneralizedRCNN) -> None:
        super().__init__()
        self.backbone = model.backbone
        self.rpn_head = model.proposal_generator.rpn_head
        self.in_features = model.proposal_generator.in_features

    def forward(self, x):
        features = self.backbone(x)
        features_ = [features[f] for f in self.in_features]
        return self.rpn_head(features_), features
```

```
# Create the wrapper with the combined backbone and RPN Head
predictor = get_model()
backbone_rpn_wrapper = NeuronFusedBackboneRPNHead(predictor.model)
backbone_rpn_wrapper.eval()

# Compile the wrapper
example = torch.rand([1, 3, 800, 800])

with torch.no_grad():
    neuron_backbone_rpn_head = torch_neuron.trace(
        backbone_rpn_wrapper, example, strict=False)
```

(continues on next page)

            # (N, A, Hi, Wi) -> (N, Hi, Wi, A) -> (N, Hi*Wi*A)
            score.permute(0, 2, 3, 1).flatten(1)
            for score in pred_objectness_logits
        ]
        pred_anchor_deltas = [
            # (N, A*B, Hi, Wi) -> (N, A, B, Hi, Wi) -> (N, Hi, Wi, A, B) -> (N, Hi*Wi*A,␣
↪B)
            x.view(x.shape[0], -1, self._rpn.anchor_generator.box_dim,
                   x.shape[-2], x.shape[-1])
            .permute(0, 3, 4, 1, 2)
            .flatten(1, -2)
            for x in pred_anchor_deltas
        ]

        proposals = self._rpn.predict_proposals(
            anchors, pred_objectness_logits, pred_anchor_deltas, images.image_sizes
        )
        return proposals, features
```

```
class NeuronRCNN(torch.nn.Module):
    """
    Wrapper that uses the fused backbone + RPN module and re-writes
    the rest of the R-CNN `model` `forward` function.
    """
```

(continues on next page)

(continued from previous page)

```
    def __init__(self, model: GeneralizedRCNN) -> None:
        super().__init__()

        # Use the fused Backbone + RPN
        self.backbone_rpn = BackboneRPN(model)

        self.roi_heads = model.roi_heads

        self.preprocess_image = model.preprocess_image
        self._postprocess = model._postprocess

    def forward(self, batched_inputs):
        images = self.preprocess_image(batched_inputs)
        proposals, features = self.backbone_rpn(images)
        results, _ = self.roi_heads(images, features, proposals, None)
        return self._postprocess(results, batched_inputs, images.image_sizes)
```

```
# Create the new NeuronRCNN wrapper with the combined backbone and RPN Head
predictor = get_model()
neuron_rcnn = NeuronRCNN(predictor.model)
neuron_rcnn.eval()

# Inject the Neuron compiled models
neuron_rcnn.backbone_rpn.backbone_rpn_head = neuron_backbone_rpn_head

# Print the R-CNN architecture to verify the compiled modules show up
print(neuron_rcnn)
```

```
# Run inference and print inference latency
start = time.time()
for _ in range(10):
    outputs = neuron_rcnn([inputs])[0]
print(f'Inference time: {((time.time() - start)/10):0.3f} s')
```

```
with profiler.profile(record_shapes=True) as prof:
    with profiler.record_function("model_inference"):
        neuron_rcnn([inputs])
print(prof.key_averages().table(sort_by="cpu_time_total", row_limit=30))
```

By running the fused backbone + RPN Head on Inf1, the overall runtime is improved again. We now see a single `neuron::forward_v2` operator with a lower runtime than the previous combined runtime of the two separate `neuron::forward_v2` operators.

Compiling the RoI Heads

In this section, we extract and compile part of RoI Heads module (predictor.model.roi_heads L530-L778). This will run most of the remaining `aten::linear` and `aten::addmm` operators on Inf1. We cannot extract the entire RoI Heads module because it contains unsupported operators. Thus, we create a `NeuronBoxHeadBoxPredictor` wrapper that extracts specific parts of the `roi_heads` for compilation. The example input for compilation is the shape of the input into the `self.roi_heads.box_head.forward` function. We write another wrapper, `ROIHead` that combines the compiled `roi_heads` into the rest of the RoI module. The `_forward_box` and `forward` functions are from the `predictor.model.roi_heads` module. We re-write the `NeuronRCNN` wrapper to use the optimized RoI Heads wrapper as well as the fused backbone + RPN module.

```
class NeuronBoxHeadBoxPredictor(torch.nn.Module):
    """
    Wrapper that extracts the RoI Box Head and Box Predictor
    for compilation.
    """

    def __init__(self, model: GeneralizedRCNN) -> None:
        super().__init__()
        self.roi_heads = model.roi_heads

    def forward(self, box_features):
        box_features = self.roi_heads.box_head(box_features)
        predictions = self.roi_heads.box_predictor(box_features)
        return predictions
```

```
# Create the NeuronBoxHeadBoxPredictor wrapper
predictor = get_model()
box_head_predictor = NeuronBoxHeadBoxPredictor(predictor.model)
box_head_predictor.eval()

# Compile the wrapper
example = torch.rand([1000, 256, 7, 7])
neuron_box_head_predictor = torch_neuron.trace(box_head_predictor, example)

roi_head_filename = 'box_head_predictor.pt'
torch.jit.save(neuron_box_head_predictor, roi_head_filename)
```

```

```

Although the overall latency didn't change significantly, running more of the model on Inf1 instead of CPU will free up CPU resources when multiple models are running in parallel.

19.5.6 End-to-end Compilation and Inference

In this section we provide standalone code that compiles and runs an optimized Detectron2 R-CNN on Inf1. Most of the code in this section is from the previous sections in this application note and it's consolidated here for easy deployment. This section has the following main componennts:

1. Preprocessing and compilation functions
2. Wrappers that extract the R-CNN ResNet backbone, RPN Head, and RoI Head for compilation on Inf1.
3. A `NeuronRCNN` wrapper that creates an optimized end-to-end Detectron2 R-CNN model for inference on Inf1
4. Benchmarking code that runs parallelized inference for optimized throughput on Inf1

Benchmarking

In the benchmarkinng section, we load multiple optimized RCNN models and run them in parallel to maximize throughput.

We use the experimental NeuronCore placement API, `torch_neuron.experimental.neuron_cores_context()`, to ensure all compiled models in an optimized RCNN model are loaded onto the same NeuronCore. Please note that the functionality and API of `torch_neuron.experimental.neuron_cores_context()` might change in future releases.

We define a simple benchmark function that loads four optimized RCNN models onto four separate NeuronCores, runs multithreaded inference, and calculates the corresponding latency and throughput. We benchmark various numbers of loaded models to show the impact of parallelism.

We observe that throughput increases (at the cost of latency) when more models are run in parallel on Inf1. Increasing the number of worker threads also improves throughput.

Other improvements

There are many additional optimizations that can be applied to RCNN models on Inf1 depending on the application:

For latency sensitive applications:

- Each of the five layers in the RPN head can be parallelized to decrease the overall latency.
- The number of OMP Threads can be increased in the ROI Align kernel. Both of these optimizations will improve latency at the cost of decreasing throughput.

For throughput sensitive applications:

- The input batch size can be increased to improve the NeuronCore utilization.

ROADMAP

The AWS Neuron feature roadmap provides visibility onto what we are working on in terms of functional and performance in the near future. We hope this will help you better plan how to use Neuron with your products. We'd love to get our customers feedback as well, to help us ensure we are working on the most important requests.

24.1 SDK Maintenance Policy

Table of Contents

- *Overview*
- *Neuron SDK*
- *Dependency Software*
- *Neuron SDK version life-cycle*
- *Dependency Software version life-cycle*
- *Communication*

24.1.1 Overview

This document outlines the maintenance policy for AWS Neuron Software Development Kit (SDK) and its underlying dependencies. AWS regularly provides the Neuron SDK with updates that may contain support for new or updated APIs, new features, enhancements, bug fixes, security patches, or documentation updates. Updates may also address changes with dependencies, language runtimes, and operating systems. Neuron SDK releases are available as Conda (up to Neuron 1.13.0) and Pip Packages that can be installed within Amazon Machine Images (AMIs).

We recommend users to stay up-to-date with SDK releases to keep up with the latest features, security updates, and underlying dependencies. Continued use of an unsupported SDK version is not recommended and is done at the user's discretion.

24.1.2 Neuron SDK

AWS Neuron is the SDK for AWS Inferentia, the custom designed machine learning chips enabling high-performance deep learning inference applications on EC2 Inf1 instances. Neuron includes a deep learning compiler, runtime and tools that are natively integrated into TensorFlow, PyTorch and MXNet. With Neuron, you can develop, profile, and deploy high-performance inference applications on top of EC2 Inf1 instances.

The Neuron SDK release versions are in the form of X.Y.Z where X represents the major version and Y represent the minor version. Increasing the major version of an SDK indicates that this SDK underwent significant and substantial changes, and some of those changes may not maintain the same programming model. Increasing the minor version of an SDK indicates that this SDK underwent addition of new features, support of new dependency software versions, end-of-support of certain dependency software, enhacement and/or bugfixes. Applications may need to be updated in order for them to work with the newest SDK version. It is important to update major versions carefully and in accordance with the upgrade guidelines provided by AWS.

24.1.3 Dependency Software

Neuron SDK has underlying dependencies, such as language runtimes, operating systems, or third party libraries and machine learning frameworks. These dependencies are typically tied to the language community or the vendor who owns that particular component. The following terms are used to classify underlying dependencies:

- Operating system (OS): Examples include Amazon Linux AMI, Amazon Linux 2.
- Language runtime: Examples include Python.
- Third party library / framework: Examples include PyTorch, TensorFlow, MXNet and ONNX.

Each community or vendor maintains their own versioning policy and publishes their own end-of-support schedule for their product.

24.1.4 Neuron SDK version life-cycle

The life-cycle for Neuron SDK version consists of 3 phases, which are outlined below.

- **Supported (Phase 1)**

  During this phase, AWS will provide critical bugfixes and security patches. Usually AWS will support each Neuron SDK version for at least 12 months, but AWS reserves the right to stop supporting an SDK version before the 12 months period.

  Note: AWS will address new features or Dependency Software updates by publishing a new version with an increment in the Neuron SDK minor version.

- **End-of-Support Announcement (Phase 2)**

  AWS will announce the End-of-Support phase at least 3 months before a specific Neuron SDK version enters End-of-Support phase. During this period, the SDK will continue to be supported.

- **End-of-Support (Phase 3)**

  When a Neuron SDK version reaches end-of support, it will no longer receive critical bugfixes and security patches. Previously published Neuron SDK versions will continue to be available via Conda (up to Neuron 1.13.0) or Pip packages. Use of an SDK version which has reached end-of-support is done at the user's discretion. We recommend users to upgrade to the latest Neuron SDK version.

24.1.5 Dependency Software version life-cycle

The life-cycle for Dependency Software version consists of 4 phases, but there may not be a Phase 3 (Maintenance) period in some cases. The phases are outlined below.

- **Supported (Phase 1)**

  During this phase, Dependency Software version is supported. AWS will provide regular updates, bug fixes and/or security patches to the Dependency Software version, AWS will address those updates and bug fixes by including them in a new Neuron SDK version with an increment in the Neuron SDK minor version. There is no minimum support period for a Dependency Software version.

- **Maintenance and/or End-of-Support Announcement (Phase 2)**

  AWS will announce the Maintenance phase or the End-of-Support phase of Dependency Software version.

  Since each community or vendor maintains their own versioning policy and publishes their own end-of-support schedule for their product, there is no minimum duration to do the announcement before Dependency Software version enters Maintenance phase or End-of-Support phase and in some cases the announcement can happen at the same time when the Dependency Software version enters Maintenance phase or End-of-Support phase.

  During this period, the Dependency Software version will continue to be supported.

- **Maintenance (Phase 3)**

  During the maintenance phase, AWS limits Dependency Software version to address critical bug fixes and security issues only. There is no minimum Maintenance period.

  This phase is optional and AWS will reserve the right to skip it for specific Dependency Software products.

- **End-of-Support (Phase 4)**

  When a Dependency Software version reaches end-of support, it will no longer receive updates or releases. Previously published releases will continue to be available via Conda (up to Neuron 1.13.0) or Pip packages. Use of an SDK which has reached end-of-support is done at the user's discretion. We recommend users to upgrade to the new major version.

  When a Dependency Software version reaches end-of support, it will no longer receive critical bugfixes and security patches. Previously published Dependency Software versions will continue to be available via Neuron SDK Conda (up to Neuron 1.13.0) or Pip packages.

  Use of a Dependency Software version which has reached end-of-support is done at the user's discretion. We recommend users to upgrade to the latest Neuron SDK version that include the latest Dependency Software versions.

Note: AWS reserves the right to stop support for an underlying dependency without a maintenance phase.

24.1.6 Communication

Maintenance and End-Of-Support announcements are communicated as follows:

- Neuron SDK documentation.

To see the list of available Neuron SDK versions and supported Dependency Software versions see neuron-release-content and *What's New* in latest Neuron version.

24.2 Security Disclosures

If you think you've found a potential security issue, please do not post it in the Issues. Instead, please follow the instructions here (https://aws.amazon.com/security/vulnerability-reporting/) or email AWS security directly (mailto:aws-security@amazon.com).

24.3 Contact Us

For support please checkout the Github issues or Neuron AWS forums for an answer, if none of those resources have an answer to your question please open a ticket.

If you have an urgent need for a feature you can also contact us directly at aws-neuron-support@amazon.com.
